Exhibit 1 - Notice of Proposed Rule Change *			The Notice section of this Form 19b-4 must comply with the guidelines for publication in the Federal Register as well as any requirements for electronic filing as published by the Commission (if applicable). The Office of the Federal Register (OFR) offers guidance on Federal Register publication requirements in the Federal Register Document Drafting Handbook, October 1998 Revision. For example, all references to the federal securities laws must include the corresponding cite to the United States Code in a footnote. All references to SEC rules must include the corresponding cite to the Code of Federal Regulations in a footnote. All references to Securities Exchange Act Releases must include the release number, release date, Federal Register cite, Federal Register date, and corresponding file number (e.g., SR-[SRO]-xx-xx). A material failure to comply with these guidelines will result in the proposed rule change being deemed not properly filed. See also Rule 0-3 under the Act (17 CFR 240.0-3)

1.   Text of the Proposed Rule Change

(a)   The Nasdaq Stock Market LLC ("Nasdaq" or "Exchange"), pursuant to

Section 19(b)(1) of the Securities Exchange Act of 1934 ("Act")[1] and Rule 19b-4

thereunder,[2] is filing with the Securities and Exchange Commission ("SEC" or

"Commission") a proposal to amend Rules 4702(b)(14) and (b)(15) of the Exchange's

Rulebook to replace the static holding period requirements for Midpoint Extended Life

Orders and Midpoint Extended Life Orders Plus Continuous Book with dynamic holding

periods. This Amendment No. 2 supersedes the original filing and Amendment No. 1[3] in

their entireties.

A notice of the proposed rule change for publication in the Federal Register is

attached as Exhibit 1.

The text of the proposed rule change is attached as Exhibit 5.

(b)   Not applicable.

(c)   Not applicable.

2.   Procedures of the Self-Regulatory Organization

The proposed rule change was approved by the Board of Directors of the

Exchange (the "Board") on October 26, 2022. No other action is necessary for the filing

of the rule change.

Questions and comments on the proposed rule change may be directed to:

Brett Kitt
AVP and Principal Associate General Counsel

3.   <u>Self-Regulatory Organization's Statement of the Purpose of, and Statutory Basis for, the Proposed Rule Change</u>

         a.   <u>Purpose</u>

The Exchange proposes to amend Rules 4702(b)(14) and (15) of the Exchange's Rulebook to replace the static 10 millisecond holding period requirements for its Midpoint Extended Life Order ("M-ELO") and Midpoint Extended Life Order Plus Continuous Book ("M-ELO+CB") Order Types with dynamic holding periods ("Dynamic M-ELO and M-ELO+CB" or collectively, "Dynamic M-ELO").

<u>Background</u>

In 2018, the Exchange introduced the M-ELO, which is a Non-Displayed Order priced at the Midpoint between the National Best Bid and Offer ("NBBO") and which is eligible for execution only against other eligible M-ELOs and only after a minimum of one-half second passes from the time that the System accepts the order (the "Holding Period").[4] In 2019, the Exchange introduced the M-ELO+CB, which closely resembles the M-ELO, except that a M-ELO+CB may execute at the midpoint of the NBBO, not only against other eligible M-ELOs (and M-ELO+CBs), but also against Non-Displayed Orders with Midpoint Pegging and Midpoint Peg Post-Only Orders ("Midpoint Orders") that rest on the Continuous Book for at least one-half second and have Trade Now enabled.[5]

---

[4]   <u>See</u> Securities Exchange Act Release No. 34-82825 (March 7, 2018), 83 FR 10937 (March 13, 2018) (SR-NASDAQ-2017-074) ("M-ELO Approval Order").

[5]   <u>See</u> Securities Exchange Act Release No. 34-86938 (September 11, 2019), 84 FR 48978 (September 17, 2019) (SR-NASDAQ-2019-048) ("M-ELO+CB Approval Order").

When the Exchange designed M-ELO, it originally set the length of the Holding Period at one-half second because it determined that this time period would be sufficient to ensure that likeminded investors would interact only with each other, and with minimal market impacts. The Exchange believed that the longer length of the M-ELO Holding Period and its simplicity in design would provide greater protection for participants than they could achieve through competing delay mechanisms.

In 2020, however, the Exchange shortened the length of the Holding Period to 10 milliseconds.[6] The Exchange did so after studying two years of actual use and performance of M-ELOs, as well as customer feedback. That is, the Exchange came to understand that, while users of M-ELO and M-ELO+CB are less concerned with achieving rapid executions of their Orders than are other participants, they are not indifferent about the length of time in which their M-ELOs and M-ELO+CBs must wait before they are eligible for execution. Indeed, participants informed the Exchange that in certain circumstances, such as when they sought to trade symbols that on average had a lower time-to-execution than a half-second, they were reticent to enter M-ELOs or M-ELO+CBs. They indicated that the associated Holding Periods for these Order Types were longer than necessary to achieve the desired protections and that, during the residual portion of the Holding Periods, they risked losing out on favorable execution opportunities that would otherwise be available to them had they placed a non-MELO order.

---

6   See Securities Exchange Act Release No. 34-88743 (April 24, 2020), 85 FR 24068 (April 30, 2020) (SR-NASDAQ-2020-011) ("M-ELO Timer Approval Order").

Based upon this feedback, the Exchange studied the potential effects of reducing

the length of the Holding Periods for both M-ELOs and M-ELO+CBs (as well as for

Midpoint Orders that would execute against M-ELO+CBs). Ultimately, the Exchange

determined that it could reduce the Holding Periods to 10 milliseconds without

compromising the protective power that M-ELO and M-ELO+CB are intended to provide

to participants and investors.[7] Thus, the Exchange determined that shortening the

Holding Periods to 10 milliseconds for M-ELOs and M-ELO+CBs would increase the

efficacy of the mechanism while not undermining the power of those Order Types to

fulfill their underlying purpose of minimizing market impacts. At the same time, the

Exchange determined that a reduction in the Holding Periods to 10 milliseconds would

dramatically add to the circumstances in which M-ELOs and M-ELO+CBs would be

useful to participants. In its M-ELO Timer Approval Order, the Commission agreed with

the Exchange:

The Commission notes that, with the proposed ten-millisecond Holding Period

and Resting Period, M-ELOs and M-ELO+CBs would continue to be optional order types

that are available to investors with longer investment time horizons, including

institutional investors. The Commission also believes that the proposal could make M-

---

[7]   The Exchange examined each of its historical M-ELO executions to determine at what Midpoints
        of the NBBO the M-ELOs would have executed if their Holding Periods had been shorter than
        one-half second (500 milliseconds). After examining the historical effects of shorter Holding
        Periods of between 10 milliseconds and 400 milliseconds, the Exchange determined that a
        reduction of the M-ELO Holding Period to as short as 10 milliseconds would have caused an
        average impact on mark-outs of only 0.10 basis points (across all symbols). In other words,
        compared to the execution price of an average M-ELO with a one-half second Holding Period, the
        Exchange found that a M-ELO with a 10 millisecond Holding Period would have had an average
        post-execution impact that was only a tenth of a basis point per share – a difference in protective
        effect that is immaterial. See Nasdaq, "The Midpoint Extended Life Order (M-ELO); M-ELO
        Holding Period," available at https://www.nasdaq.com/articles/the-midpoint-extended-life-order-
        m-elo%3A-m-elo-holding-period-2020-02-13 (analyzing effects of shortened Holding Periods on
        M-ELO performance).

ELOs and M-ELO+CBs more attractive for securities that on average have a time-to-execution of less than one-half second and, for investors who currently do not use M-ELOs and M-ELO+CBs for these securities, provide optional order types that could enhance their ability to participate effectively on the Exchange. The Commission notes that, if market participants determine that the proposal would make M-ELOs and M-ELO+CBs less attractive for their particular investment objectives, such market participants may elect to reduce or eliminate their use of these optional order types. Moreover, as noted above, the Exchange will continue to conduct real-time surveillance to monitor the use of M-ELOs and M-ELO+CBs to ensure that such usage remains appropriately tied to the intent of the order types. If, as a result of such surveillance, the Exchange determines that the shortened Holding Period does not serve its intended purpose or adversely impacts market quality, the Exchange would seek to make further recalibrations.[8]

For similar reasons and with even better potential results for participants, the Exchange now proposes to further refine the length of the Holding Periods for M-ELOs and M-ELO+CBs, this time through the application of innovative and patent pending machine learning technology.

Dynamic M-ELO

After receiving feedback from participants that even 10 millisecond Holding Periods for M-ELO and M-ELO+CB may, at times, exceed what is necessary to accomplish the underlying intent of these Order Types, the Exchange began to experiment with making further refinements to the duration of the Holding Periods.

---

[8]   M-ELO Timer Approval Order, supra, at 85 FR 24069.

Ultimately, the Exchange concluded that shorter Holding Periods could achieve the same, if not better results for participants in terms of mark-outs, but not in all circumstances. That is, where prices of the underlying securities are stable, and not subject to imminent unfavorable changes, M-ELOs and M-ELO+CBs face lower risks of confronting spread-crossing orders, such that shorter Holding Periods could suffice to protect M-ELOs and M-ELO+CB from such orders. In periods of heightened price volatility, however, M-ELOs and M-ELO+CBs also face heightened risks, such that longer Holding Periods would continue to be beneficial in protecting M-ELOs and M-ELO+CBs from such risks. Thus, the Exchange determined that another across-the-board reduction of the static 10 millisecond Holding Periods would be sub-optimal because it could impact the performance of the M-ELO and M-ELO+CB Order Types during periods of heightened volatility.

In light of these observations, the Exchange tasked its artificial intelligence and machine learning laboratory (the "AI Core Development Group") to explore whether it could employ these innovative technologies to optimize the length of M-ELO and M-ELO+CB Holding Periods during various states of price volatility, and then to vary the lengths of the Holding Periods dynamically during the lifecycles of M-ELOs and M-ELO+CBs, with the objectives of improving the performance of these Order Types while also further reducing opportunity costs.

As the Exchange explains in greater depth in the attached white paper, [9] the AI Core Development Group proceeded to develop an artificial intelligence-based timer

---

[9]   See Diana Kafkes et al., "Applying Artificial Intelligence & Reinforcement Learning Methods Towards Improving Execution Outcomes," SSRN, October 19, 2022, available at

control system that will achieve these objectives. [10] The AI Core Development Group did

so by using reinforcement learning techniques – machine learning paradigms which

develop optimal solutions to problems over time by taking actions to solve them,

generating feedback on the results of such actions, applying that feedback to direct and

improve the next round of solutions, and then repeating the feedback loop until the

paradigm achieves optimized solutions.

In this instance, the AI Core Development Group applied reinforcement learning

techniques to a simulation of the M-ELO Book that it constructed using a representative

data set from the first quarter of 2022 (the "Training Period"). The Training Period data

consisted of 380 out of the 6,257 symbols on the M-ELO Book (accounting for

approximately 67 percent of M-ELO volume). The symbols chosen reflect both actively-

traded and thinly-traded securities, and both low-priced and high-priced securities.

The AI Core Development Group then developed a machine learning model and

applied it to the Training Period data. The Group programmed the model to value the

achievement of higher fill rates or lower mark-outs than that which occurred in a

historical simulation of M-ELOs and M-ELO+CBs involving the Training Period data. [11]

---

https://papers.ssrn.com/sol3/papers.cfm?abstract_id=4243985 (attached hereto without
modification from the prior version as Exhibit 3(a)) (the "White Paper").

[10]   Although the AI Core Development Group acknowledges that an optimal Holding Period would
update with every incoming order, it determined that training a reinforcement learning model on
every order would be too difficult to program and too difficult to implement given the nanosecond
latency requirements of the Exchange. The Group then investigated more feasible update
cadences and determined the point at which optimal outcomes were best balanced with the level of
programming and implementation difficulty to be between 15 and 30 second updates. Ultimately,
the Group chose a 30 second update cadence to give the model the greatest opportunity to learn
between potential actions.

[11]   As the White Paper explains, the Group developed a model to simulate activity on the Exchange
involving M-ELOs and M-ELO+CBs during the Training Period. See White Paper, supra, at 10.

The Group then programmed the model to seek to achieve its goals by taking one of five possible actions with respect to the duration of the Holding Periods at 30 second intervals[12] for each symbol during each trading day of the Training Period. That is, at each 30 second internal, the model evaluated market conditions for each symbol over the prior 30 second period and either kept the Holding Periods the same, increased/decreased them by 0.25 milliseconds, or increased/decreased them by 0.50 milliseconds.[13]   After each decision-making round, the model utilized the results to inform its actions at the next 30 second increment.

In making its decisions, the model (again, drawing upon a combination of historical SIP and M-ELO-specific data) considered 142 categories of data points. [14]   A confluence of data points that correlated with an increase in volatility tended to cause the model to increase the durations of Holding Periods, including increases in the standard deviation of NBBO prices, the number of unique participants placing sell orders on M-ELO and M-ELO+CB, and the volume-weighted average of the NBBO spread. Conversely, a confluence of data points that correlated with greater price stability tended to cause the model to decrease the durations of Holding periods, such as an increase in

---

[12]   See id.

[13]   The AI Core Development Group experimented with a range of permissible Holding Period durations. Ultimately, it concluded that it could produce better outcomes for M-ELO and M-ELO+CB participants than the existing approach using Holding Periods as low as 0.25 milliseconds and as high as 2.5 milliseconds, under normal market conditions.

[14]   Nasdaq attaches a full list of these data elements (attached hereto as "Exhibit 3(b)"), along with an observation of the strength of the correlations that currently exist between changes to those data values and decisions the system makes to set the duration of Holding Periods at any given time. The Exchange notes that the version of this list attached to this Amendment No. 2 supersedes prior versions attached to prior versions of this filing. This version of the list includes expanded explanations of the terminology used therein. See also White Paper, supra, at 31, for a description of these features.

the median and max number of shares per trade and the number of resting bids left in the M-ELO and M-ELO+CB Book.

The AI Core Development Team produced variations of its model that prioritized achievement of the lowest mark-outs, the highest fill rates, and a blend of these two objectives. [15] Through a process of learning and experimentation involving a combination of historical and simulated data, the AI Core Development Group settled on a Dynamic M-ELO model that achieved substantial simulated performance improvements for users of M-ELO and M-ELO+CB – both in terms of mark-outs and fill rates – as compared to the static 10 millisecond Holding Periods. As the White Paper explains in greater detail, Dynamic M-ELO yielded an average combined volume-weighted (simulated) improvement of 31.7 percent, including a 20.3 percent increase in fill rates and a 11.4 percent reduction in mark-outs. [16] The White Paper provides a more fulsome explanation of these improvements.[17]

Based upon these exciting results, the Exchange now proposes to amend Rule 4702(b)(14) and (15) to replace the static 10 millisecond timers applicable to M-ELO and M-ELO+CB with Dynamic M-ELO Holding Periods. Using the Exchange's "proprietary

---

[15]   The AI Core Development Group also applied to the model a paradigm called "retraining" to combat the degradation of model performance that can otherwise occur as the reference data it uses for initial comparison becomes stale. Finally, the AI Core Development group added a stability protection mechanism to the model to provide maximum production to participants in the event that the model observes extraordinary levels of instability in the National Best Bid and Offer during the prior three seconds as compared to reference data. When the model detects such instability, it is programmed to increase the length of the Holding Period to 12 milliseconds for a period of 750 milliseconds.

[16]   See White Paper, supra, at 22.

[17]   See id.

assessment of market conditions"[18] and patent pending technology, the Dynamic M-ELO

system will evaluate and, as it deems necessary, adjust the length of the Holding Periods

for each symbol comprising M-ELOs and M-ELO+CBs (and Midpoint Orders on the

Continuous Book that opt to interact with M-ELO+CBs after resting on the Book) every

30 seconds throughout the Market Hours (each such 30 second interval, a "Change

Event"). In so doing, Dynamic M-ELO will help participants to achieve a more

optimized blend of the underlying purposes of the M-ELO and M-ELO+CB Order Types:

protection against adverse selection (low mark-outs) without sacrificing opportunities to

achieve high-quality executions (high fill rates).

     A proposed M-ELO or M-ELO+CB with a Dynamic Holding Period will operate

as follows. At the outset of Market Hours (approximately 9:30:00 AM), the Exchange

will impose initial Holding Periods of 1.25 milliseconds for M-ELOs and M-ELO+CBs

in all symbols. Thereafter, Holding Periods for a given symbol will become eligible to

change dynamically from the initial duration beginning at 9:30:30AM and then at 30

second intervals thereafter during Market Hours. The Exchange will then apply to the M-

ELO or M-ELO+CB Order a Holding Period that is of the duration that prevailed at the

---

18   As set forth in the proposed rule text, the phrase "proprietary assessment of market conditions" refers to the Exchange's evaluation of prevailing market conditions for a given symbol using an algorithm programmed to set a Holding Period duration which, at each Change Event, achieves an optimal blend of two objectives: maximization of M-ELO fill rates; and minimization of M-ELO mark-out rates. As the rule text states and as is discussed below, the algorithm ingests and analyzes 142 data points, which the Exchange identifies and describes in Exhibit 3b hereto. The Exchange derives these data from a combination of public data and M-ELO data feeds. Furthermore, the Exchange conducts weekly re-trainings of the algorithm, outside of Market Hours, to improve its performance relative to the immediately preceding period (in terms of the two aforementioned objectives). The Exchange deploys a retrained version of the algorithm only if it determines that doing so will, in fact, improve its performance relative to the immediately preceding period. The Exchange provides further information about the algorithm and the retraining process in a White Paper attached hereto as Exhibit 3a.

time of entry. For example, if participant A enters a M-ELO for symbol XYZ at 9:30:25

AM, then Holding Period for that M-ELO will be 1.25 milliseconds. If at 9:30:30:00

AM, the System decides to lower the duration of the Holding Period by 0.50

milliseconds, and then participant B enters a M-ELO for symbol XYZ at 9:30:45 AM,

then the System will assign a 0.75 millisecond Holding Period to participant B's M-ELO.

To be clear, the System will determine Dynamic M-ELO Holding Periods independently

for M-ELOs and M-ELO+CBs in each symbol.

During normal market conditions, the range of potential Holding Period durations

for M-ELOs and M-ELO+CBs will be between 0.25 – 2.50 milliseconds, with the

Holding Period duration being eligible to change by increments of either 0.25 or 0.50

milliseconds at each Change Event. Thus, if the Holding Period for a M-ELO in symbol

XYZ is set at 0.75 milliseconds at 2:22:11 PM, and at 2:22:41 PM, the System

determines to increase the duration of the Holding Period, it may do so only by 0.25 or

0.50 milliseconds during that event.

When a Change Event occurs, and the System determines to adjust the duration of

a Holding Period for a symbol, that adjustment will apply, not only to all M-ELOs and

M-ELO+CBs for that symbol entered within the 30 second period after the Change Event

occurs, but also to M-ELOs and M-ELO+CBs entered prior to the Change Event with

unexpired Holding Periods (with applicability retroactive to the time of Order

acceptance). Thus, if a participant enters a M-ELO in symbol XYZ at 1:14:299 PM, and

the prevailing Holding Period applicable to that M-ELO is 2 milliseconds, and at 1:14:30

PM, the System modifies the Holding Period to be 1.5 milliseconds, then the M-ELO will

become eligible to execute at 1:14:3005 P.M. This is the case because the M-ELO will

have already expended 1 millisecond of its Holding Period as of the time of the Change

Event; thereafter, the M-ELO will need to rest only another 0.5 milliseconds to become

eligible to execute under the new 1.5 millisecond Holding Period (as measured from

1:14:299 PM). This last feature ensures that the M-ELO Book maintains time priority

among M-ELOs and M-ELO+CBs in a dynamic environment. That is, it ensures that no

M-ELO or M-ELO+CB with an unexpired Holding Period at the time of a Change Event

will end up becoming eligible to execute later than a M-ELO entered after the Change

Event which has a shorter Holding Period applicable to it.

If at any time, the System detects extraordinary instability in a symbol, then the

System will activate a "stability protection mechanism" to provide an extra layer of

protection to M-ELO and M-ELO users from the heightened risks of adverse selection

that exists during such periods of instability.[19] The stability protection mechanism will

override the prevailing Holding Periods for M-ELOs and M-ELO+CBs in a symbol

experiencing extraordinary instability and immediately increase the duration of those

Holding Periods to 12 milliseconds for a period of 750 milliseconds. The System may

activate the stability protection mechanism even between Change Events. The System

will evaluate, at each NBBO update, whether market conditions remain extraordinarily

---

[19] For purposes of this Rule, the System determines that "extraordinary instability" for a symbol exists through observations it makes following every change in the NBBO for that symbol that occurs during the trading day. When the NBBO changes, the System looks back at the prior three seconds of trading and measures the difference between the highest and the lowest NBBO midpoint values that occurred during that period, and then it compares that measurement to a threshold value for the symbol. The System concludes that extraordinary instability exists for a symbol if the measurement exceeds the threshold value.

The threshold value for a symbol, in turn, is the difference between the highest and the lowest NBBO midpoint values for the symbol that, if applied to its trading activity during the prior trading day, would have caused the System to deem trading in the symbol to be extraordinarily unstable for as close to one percent of that day as possible.

unstable and, if so, it will restart the 750 millisecond Stability Protected Period and maintain the 12 millisecond Holding Period until conditions stabilize. Once the System determines that market conditions have stabilized (i.e., all measurements for the symbol are at or below the threshold value throughout the duration of the prevailing Stability Protected Period), the System will revert the duration of the Holding Periods to that which prevailed as of the Change Event that occurred immediately prior to the activation of the stability protection mechanism or, if the stability protection mechanism was active when a Change Event occurred, to the duration selected at the immediately preceding Change Event. The System will then proceed to reevaluate the duration of the Holding Periods as per the regular schedule of Change Events.

The following is an illustration of the operation of the stability protection mechanism. At 11:10:04 AM, the prevailing Holding Period for M-ELOs in symbol XYZ is 1.5 milliseconds. At the same time, the NBBO for symbol XYZ updates. The System looks back at the prior three seconds of trading in symbol XYZ and finds that during that period, the highest observed NBBO midpoint was $10.05, and the lowest was $10.00, such that the difference between these two values is a range of $0.05. The System then looks back at trading behavior for symbol XYZ during the immediately preceding trading day. In doing so, the System calculates the value of the threshold that would have caused the symbol to be deemed extraordinarily unstable for one percent of the trading day; the System determines that this threshold value is a range of $0.03. The System then compares the $0.03 threshold to its measurement of the prior three seconds of NBBO changes ($0.05), and concludes that over these past three seconds, the symbol is extraordinarily unstable. Accordingly, the System activates the stability protection

mechanism and the Holding Period for M-ELOs in symbol XYZ immediately increases

to 12 milliseconds for a period of 750 milliseconds. However, 5 milliseconds after the

Stability Protection Period commences, the NBBO updates again, thus prompting the

System to repeat its assessment of the stability of the symbol in light of the update. This

reassessment reveals that the symbol remains unstable, such that a new Stability

Protection Period of 750 milliseconds begins at that time (overriding the pre-existing

Period). Over the course of this new Stability Protection Period, the NBBO shifts two

more times, but each of the ensuing reassessments indicate that the NBBO ranges for the

symbol have fallen below the $0.03 threshold. The Stability Protection Period elapses

750 milliseconds after it began with the symbol remaining stable. Thus, the Holding

Period reverts to 1.5 milliseconds.

If the Exchange halts trading in a symbol, then upon resumption of trading, any

new M-ELO or M-ELO+CB in that symbol and any pending M-ELO or M-ELO+CB in

that symbol with an unexpired Holding Period will be subject to a new 12 milliseconds

Holding Period (running from the time when trading resumes) until the next scheduled

Change Event, at which point the System may determine to adjust that Holding Period to

a duration within the range applicable under normal market conditions. [20] If, however,

the System determines that extraordinary instability in the symbol exists, it will instead

determine to activate the stability protection mechanism and maintain the duration of the

Holding Period at 12 milliseconds for another 750 milliseconds. This design will help to

---

[20]   Prior to commencement of a new 12 millisecond Holding Period for a new or pending M-ELO or
        M-ELO+CB following a Halt, the System will first determine whether the M-ELO or M-ELO+CB
        is or remains eligible for execution. That is, the Holding Period will commence only if, upon
        commencement of trading following the Halt, the midpoint price for the Order is within the limit
        set by the participant. If not, the System will hold the Order until the midpoint falls within the
        limit set by the participant, at which time the 12 millisecond Holding Period will commence.

ensure that M-ELOs and M-ELO+CBs receive added protection coming out of halt conditions.[21]

The Exchange notes that same dynamic process described above will also apply to and govern the time periods during which Midpoint Orders on the Continuous Book must rest before they will become eligible to interact with M-ELO+CBs (provided that participants have opted for their Midpoint Orders to interact with M-ELO+CBs). Thus, the same Holding Period duration that the System sets for a M-ELO+CB in a symbol during Regular Market Hours will also be the length of time that a Midpoint Order must rest on the Continuous Book must rest before it may interact with a M-ELO+CB.

Apart from these impacts of Dynamic Holding Periods, M-ELOs and M-ELO+CBs will continue to behave as they do now in all respects, and as set forth in Rules 4702(b)(14) and (15).

It is important to note that within the parameters discussed herein and in the White Paper, the Exchange will continue to re-train Dynamic M-ELO and M-ELO+CB on a weekly basis (outside of market hours) so that the model will continue to learn from and act upon the basis of more recent SIP and M-ELO book data sets, and further improve its performance over time. The retraining process should not result in dramatic or unpredictable changes to the behavior of Dynamic M-ELO. The retraining process will not retrain the model from scratch each week; rather, it will retain the model's existing data inputs, knowledge base, and objectives – all without alteration. Retraining

---

21   Also as a safeguard, the System will apply a default Holding Period of 12 milliseconds to a M-ELO or M-ELO+CB if ever it fails to receive a signal during a Change Event as to whether the System should adjust or maintain the duration of the prevailing Holding Period. The System will continue to apply the default 12 millisecond Holding Period until the next Change Event where the signal is restored and the System is able to act dynamically again.

will result in new behaviors only as needed to address new scenarios that the model did not confront previously, and even then, only in a manner designed to further optimize outcomes, i.e., reduce mark-outs or increase fill rates. If the System assesses that a retrained model would be worse than the existing model in achieving its objectives, then the System will continue to use the existing model and discard the retrained model. This retraining process is a standard and accepted practice for use of deep learning models; it helps to ensure that deep learning models not only work well, but that they continue to work well in dynamic circumstances. [22]

The Exchange will not modify the underlying structure of Dynamic M-ELO and M-ELO+CB without first obtaining the Commission's approval to do so, including modifications to the data elements the model considers in making decisions about Holding Period durations, the conditions under which the model may adjust the duration of Holding Periods, the frequency with which the model my adjust the Holding Periods, the range of Holding Period durations available to M-ELOs and M-ELO+CBs, the increments by which Holding Periods may change at any given Change Event, and the procedures for triggering, maintaining, and ending 12 millisecond Holding Periods during times of extraordinary instability.[23] Although the Exchange will seek Commission approval prior to changing any of the data elements that the model considers, the

---

[22]   During periods where the model is not undergoing retraining, the System will behave predictably from day to day, such that its decisions when presented with given set of facts and circumstances in a given security on day 1 should be the same as they would be on day 2.

[23]   In addition to the proposed changes described above, the Exchange proposes to delete an extraneous reference in Rule 4702(b)(15) to M-ELO+CB being eligible to execute against a Midpoint Order on the Continuous Book if the Continuous Book order has the "Midpoint" Trade Now Attribute enabled. In a prior filing, the Exchange folded the concept of "Midpoint Trade Now" into the general "Trade Now" Attribute. See Securities Exchange Act Release No. 34-92180 (June 15, 2021), 86 FR 33420 (June 24, 2021)(SR-NASDAQ-2021-044).

Exchange will not seek Commission approval prior to retraining the model to adjust the
weighting it applies to those data elements.

To aid investors in understanding and evaluating Dynamic M-ELO, Nasdaq will
continue to publish weekly and monthly transparency statistics on Nasdaqtrader.com, as
it does now, about the performance of its M-ELOs and M-ELO+CBs, including statistics
listing the weekly numbers of shares and trades in M-ELOs by symbol, weekly
aggregated M-ELO share and trade data, and monthly aggregated block data.[24] Nasdaq
also will continue to disclose monthly data on Nasdaq.com, as it does now (the M-ELO
Monthly Report), about M-ELO and M-ELO+CB mark-outs (quote stability by time
horizon) and fill rates. [25] Moreover, Nasdaq will add statistics to the M-ELO Monthly
Report about how frequently, on average, the System changes Holding Period durations
for the top decile, median, and bottom decile of symbols, as measured by monthly M-
ELO and M-ELO+CB trading volumes. Nasdaq will retain copies of each historical
iteration of its models as part of its books and records, and make them available to the
Commission upon request, should it wish to examine them to understand how the model
changes over time. Furthermore, Nasdaq will publish an equity trader alert in advance of
deploying a retrained version of Dynamic M-ELO whenever Nasdaq has reason to
anticipate that the retrained version will produce results that differ materially from the

---

[24]   See http://www.nasdaqtrader.com/Trader.aspx?id=MELOSymbolData.

[25]   See, e.g., https://www.nasdaq.com/docs/M-ELO-Monthly-Report.   Nasdaq understands that
         current users of M-ELO and M-ELO independently monitor the performance of these Order
         Types. Nasdaq often receives feedback from such users about M-ELO and M-ELO+CB
         performance, which Nasdaq then factors into decisions about improvements and enhancements.
         Nasdaq expects that this feedback loop will continue after implementation of Dynamic M-ELO.

prior version, i.e., a projected change in mark-outs or fill-rates of 10% or more in either direction.

The Exchange acknowledges that systems necessary to implement Dynamic MELO, including the systems proposed that include model development and retraining processes, are "SCI Systems" within the meaning of Regulation Systems Compliance and Integrity ("Reg. SCI"), [26] and that the Exchange, as an SCI Entity, remains responsible for compliance with all requirements of Reg. SCI, including, without limitation, to have policies and procedures reasonably designed to ensure that its SCI Systems operate in a manner that complies with the Act and the rules and regulations thereunder and Exchange's rules and governing documents, among them a plan for assessments of the functionality of SCI Systems designed to detect systems compliance issues, including by responsible SCI personnel and by personnel familiar with applicable provisions of the Act and the rules and regulations thereunder and Exchange's rules and governing documents.

<u>Implementation</u>

The Exchange intends to make the proposed change effective for M-ELOs and M-ELO+CBs in the Second or Third Quarter of 2023, but that time frame is subject to change. The Exchange will publish a Trader Alert in advance of making the proposed change effective.

---

[26]   17 CFR 242.1000 <u>et seq</u>. As set forth in Reg. SCI, the term "SCI Systems" means "means all computer, network, electronic, technical, automated, or similar systems of, or operated by or on behalf of, an SCI entity that, with respect to securities, directly support trading, clearance and settlement, order routing, market data, market regulation, or market surveillance." <u>Id</u>. at 242.1000. An "SCI Entity" means "an SCI self-regulatory organization, SCI alternative trading system, plan processor, exempt clearing agency subject to ARP, or SCI competing consolidator." <u>Id</u>.

b.   Statutory Basis

The Exchange believes that its proposal is consistent with Section 6(b) of the Act,[27] in general, and furthers the objectives of Section 6(b)(5) of the Act,[28] in particular, in that it is designed to promote just and equitable principles of trade, to remove impediments to and perfect the mechanism of a free and open market and a national market system, and, in general to protect investors and the public interest, by allowing for more widespread use of M-ELOs and M-ELO+CBs.

When the Commission approved the M-ELO and the M-ELO+CB, it determined that these Order Types are consistent with the Act because they "could create additional and more efficient trading opportunities on the Exchange for investors with longer investment time horizons, including institutional investors, and could provide these investors with an ability to limit the information leakage and the market impact that could result from their orders."[29] Nothing about the Exchange's proposal should cause the Commission to revisit or rethink this determination. Indeed, the proposal will not alter the fundamental design of these Order Types, the manner in which they operate, or their effects.

Even with Dynamic M-ELO Holding Periods, M-ELOs and M-ELO+CBs will continue to provide their users with protection against information leakage and adverse

---

[27]   15 U.S.C. 78f(b).

[28]   15 U.S.C. 78f(b)(5).

[29]   M-ELO Approval Order, supra 83 FR at 10938–39; M-ELO+CB Approval Order, supra, 84 FR at 48980.

selection – and they will do so at levels which are substantially undiminished from that which they provide now.[30]

At the same time, however, the proposal will benefit market participants and investors by reducing the opportunity costs of utilizing M-ELOs and M-ELO+CBs. The proposal, in other words, will re-calibrate the lengths of the Holding Periods so that M-ELOs and M-ELO+CBs will operate in the "Goldilocks" zone – their Holding Periods will not be so short as to render them unable to provide meaningful protections against information leakage and adverse selection, but the Holding Periods also will not be too long so as to cause participants and investors to miss out on favorable execution opportunities. Nasdaq believes the proposal will render M-ELOs and M-ELO+CBs more useful and attractive to market participants and investors, and this increased utility and attractiveness, in turn, will spur an increase in M-ELO and M-ELO+CB use cases on the Exchange, both from new and existing users of M-ELOs and M-ELO+CBs. Ultimately, the proposal should enhance market quality by increasing opportunities for midpoint executions on the Exchange.

As Nasdaq explained above, the Proposal will operate within strict, well-defined, and transparent parameters. Although it will undergo weekly retraining (outside of market hours),[31] such retraining will aim to improve the performance of the model in achieving its twin objectives; retraining will not alter the inputs, objectives, or basic

---

[30]   See note 6, supra.

[31]   To be clear, performance statistics for Dynamic M-ELO cited herein and in the White Paper are based upon data derived from weekly, not daily retrainings.

design parameters of Dynamic M-ELO without prior Commission approval. [32]

Moreover, the Exchange will not deploy a retrained model if it fails to achieve

performance improvements. To aid investors in evaluating Dynamic M-ELO, the

Exchange will publish statistics about its performance, including as to mark-outs and fill

rates, as well as statistics about how frequently the System changes Holding Period

durations. To further facilitate accountability, the Exchange will retain each historical

iteration of its model as part of its books and records, and make such information

available to the Commission, upon request. The Exchange will also publish equity trader

alerts whenever retraining will result in a performance change of 10% or more.

Nasdaq notes that the twin objectives it prescribes for the model involve the

absolute values of mark-outs and fill rates; they are not designed to further the

performance of any participant or any category of participant.   Furthermore, Nasdaq

performed internal tests of its AI model to detect indications of harmful bias in its

performance results, and such tests concluded that no such indications exist. That is, the

Exchange reviewed the impact on fill rates and mark-outs of Dynamic M-ELO, as

compared to the "static" M-ELO, for those firms that accounted for more than 95% of M-

ELO activity on the Exchange during Q1 2022. [33] The Exchange analyzed results both in

---

[32]   As discussed above, Nasdaq will not seek Commission approval prior to allowing the model, as part of its re-training process, to vary the weighting of the data elements it ingests. Nasdaq believes this is appropriate because such variance will only occur to the extent that it will improve the model's performance with respect to pre-defined objectives. Nasdaq will alert traders if the retraining process would result in substantial performance changes, and it will also publish statistics to help participants to assess performance themselves. Moreover, Nasdaq will retain historical iterations of its models for the Commission's review, should it wish to examine how these models have changed over time.

[33]   Beyond this grouping of participants, the activity levels of other individual M-ELO participants were so small as to be insignificant. In many cases, these participants entered only a handful of M-ELOs during the study period. As such, the Exchange believes it is reasonable to exclude such participants from its analysis to avoid their data distorting the results.

an absolute and a relative sense. Testing revealed that all participants experienced at

least some improvements in fill rates and mark-outs when using Dynamic M-ELO versus

static M-ELO, with the volume-weighted average improvement being aligned with the

results expressed in the White Paper. We detected no material variations that might

suggest that a particular participant or category of participant (i.e., nature of firm; size of

firm) benefitted from Dynamic M-ELO functionality to an extent that was unreasonably

disproportionate to the benefits that other participants experienced. Thus, Nasdaq

believes the model is objective, is designed to, and does avoid bias and discrimination. [34]

The Exchange notes that use of Dynamic M-ELOs and M-ELO+CBs remains

voluntary for all market participants. Accordingly, if any market participant feels that the

dynamic Holding Periods are still too long or too short or because competing venues

offer more attractive delay mechanisms, then the participants are free to pursue other

trading strategies or utilize other trading venues. They need not utilize Dynamic M-

ELOs or M-ELO+CBs.

Furthermore, the design of Dynamic-MELO would constitute an "established,

non-discretionary" method that is consistent with the definition of an exchange, as set

forth in SEC Rule 3b-16.[35] The Commission stated as follows when it adopted Rule 3b-

16:

---

[34]   The Exchange will review its AI model periodically to affirm that it continues to perform in
        accordance with the Exchange's rules and has not introduced any harmful bias in favor of or
        against any participant or category of participants.

[35]   See 17 CFR 240.3b-16(a)(2) ("(a) An organization, association, or group of persons shall be
        considered to constitute, maintain, or provide 'a market place or facilities for bringing together
        purchasers and sellers of securities or for otherwise performing with respect to securities the
        functions commonly performed by a stock exchange,' as those terms are used in section 3(a)(1) of
        the Act, (15 U.S.C. 78c(a)(1)), if such organization, association, or group of persons: (1) Brings
        together the orders for securities of multiple buyers and sellers; and (2) Uses established, non-

> A system uses established non-discretionary methods either by providing a trading facility or by setting rules governing trading among subscribers. The Commission intends for "established, non-discretionary methods" to include any methods that dictate the terms of trading among the multiple buyers and sellers entering orders into the system. Such methods include those that set procedures or priorities under which open terms of a trade may be determined. For example, traditional exchanges' rules of priority, parity, and precedence are "established non-discretionary methods," as are the trading algorithms of electronic systems. Similarly, systems that determine the trading price at some designated future date on the basis of pre-established criteria (such as the weighted average trading price for the security on the specified date in a specified market or markets) are using established, non-discretionary methods. [36]

Nothing in the Reg. ATS Adopting Release or in any of its illustrative examples suggests that Dynamic M-ELO would constitute an exercise of discretionary behavior. Dynamic M-ELO will handle and execute Orders according to published, pre-determined rules that are disclosed to the public and which provide reasonable notice of how the Order Type will behave.[37] To the extent that the design of the System permits variation in the Holding Periods for such Orders, it does so by design. The range of potential variations, the objectives that such variations are intended to achieve, and the factors that determine when such variations may occur are also predetermined and set forth in the Exchange's Rules or otherwise disclosed to the public. The mere fact that the System may apply different weights over time to the factors it uses to determine whether and by how much to vary a Holding Period does not mean that the System will act with discretion in the

---

discretionary methods (whether by providing a trading facility or by setting rules) under which such orders interact with each other, and the buyers and sellers entering such orders agree to the terms of a trade.").

[36]   See Securities Exchange Act Release No. 40760 (December 8, 1998), 63 FR 70844, 70850 (December 22, 1998).

[37]   See id. at 70900 ("an essential indication of the non-discretionary status of rules and procedures is that those rules and procedures are communicated to the systems users'' and ''[t]hus, participants have an expectation regarding the manner of execution—that is, if an order is entered, it will be executed in accordance with those procedures and not at the discretion of a counterparty or intermediary.").

same sense that a human being could be said to be exercise independent judgment when

deciding whether and how to handle an order.[38] Even when the System makes decisions

about changing the Holding Periods, the System will operate pursuant to a mathematical

algorithm from which it cannot deviate – an algorithm that is programmed to achieve pre-

defined and pre-disclosed objectives. [39]

The Exchange notes that it will continue to conduct real-time surveillance to

monitor the use of M-ELOs and M-ELO+CBs to ensure that such usage remains

appropriately tied to the intent of the Order Types. If, as a result of such surveillance, the

Exchange determines that the Dynamic M-ELO Holding Periods do not serve their

---

[38]   Cf. id. at 70851 (explaining that a traditional block trading desk is an example of a system that does not use established, non-discretionary methods because the operators of such desks do not act according to fixed procedures known to their customers, but instead shop orders around for potential counterparties and make their own determinations as to whether and how to execute block orders, including by sometimes deciding to take a proprietary position in part of the block order).

[39]   See id. at 80755 (describing an example of a system that would be non-discretionary in nature: "System I permits participants to enter a range of ranked contingent buy and sell orders at which they are willing to trade securities. These orders are matched based on a mathematical algorithm whose priorities are designed to achieve the participants' objectives. System I does not display orders to any participants. System I is included under Rule 3b-16."); see also Securities Exchange Act Release No. 34-89686 (August 20, 2020), 85 FR 54438, at 54445, n.92 (September 1, 2020) (Order approving SR-IEX-2019-15) (rejecting argument that IEX's D-Limit order time is an exercise of discretion because "D-Limit orders will not allow IEX to exercise any discretion on any particular order by deviating from the CQI and D-Limit functionality, which is hardcoded in the IEX rulebook."; Securities Exchange Act Release No. 34-78101 (June 17, 2016), 81 FR 41141, at 41153(June 17, 2016) (Order approving IEX Form 1 and D-Peg Order Type) ("the Commission does not believe that the hardcoded conditionality of the IEX proposed ''discretionary'' peg order type provides IEX with actual discretion or the ability to exercise individualized judgment when executing an order. Rather, if IEX's fixed formula determines the quote to be stable, the discretionary peg order can execute up to the midpoint; if it does not deem the quote to be stable, then it will hold the order to its pegged price. As such, IEX would not exercise discretion over the routing and execution of a resting order"). Nasdaq does not believe that it is necessary to codify its mathematical formula for Dynamic M-ELO in its Rules because Nasdaq has disclosed sufficient information in its Rules and in its filing to inform the public as to the possible and expected behaviors associated with Dynamic M-ELO, as well as a means for the Commission and/or investors to verify whether Dynamic M-ELO is performing appropriately. Much as the Commission does not require an exchange to codify the source code it uses to effectuate other behaviors or actions that it explains in its Rules, including the behaviors of other complex Order Types, there is no basis to require codification of the Dynamic M-ELO formula in this instance.

intended purposes, or adversely impact market quality, then the Exchange will seek to make further re-calibrations.

Nasdaq does not believe that the design of Dynamic M-ELO lends itself to potential manipulation by a single participant or a small group of participants because the System makes determinations regarding Holding Periods based upon prevailing market-wide conditions for a given symbol, rather than the behaviors of particular participants with respect to that symbol, or the activity of participants in M-ELOs involving that symbol.   Manipulation of the System also would be difficult to accomplish given the large number of variables that factor into the System's decisions to change Holding Periods during Change Events, as well as the different weighs that apply to each such factor, which as described above, the System may vary over time. Any benefits that a participant might derive from manipulating the duration of Holding Periods would likely be small and outweighed significantly by the difficulty and cost of affecting such manipulation. Nevertheless, the Exchange will surveil for indications of manipulation and act accordingly if it detects such indications.

4.   Self-Regulatory Organization's Statement on Burden on Competition

The Exchange does not believe that the proposed rule change will impose any burden on competition not necessary or appropriate in furtherance of the purposes of the Act. To the contrary, the Exchange believes that this proposal will promote the competitiveness of the Exchange by rendering its M-ELO and M-ELO+CB Order Types more attractive to participants.

The Exchange adopted the M-ELO and M-ELO+CB as pro-competitive measures intended to increase participation on the Exchange by allowing certain market participants that may currently be underserved on regulated exchanges to compete based

on elements other than speed. The proposed change continues to achieve this purpose.

With Dynamic M-ELO Holding Periods, both M-ELOs and M-ELO+CBs will afford

their users with a level of protection from information leakage and adverse selection that

is better from what is achievable at present.[40] At the same time, the Dynamic Holding

Periods will increase opportunities to interact with other like-minded investors with

longer time horizons while also lowering the opportunity costs for participants that utilize

M-ELOs and M-ELO+CBs, particularly for securities that trade within the "Goldilocks"

zone. In sum, the proposed changes will not burden competition, but instead may

promote competition for liquidity in M-ELOs and M-ELO+CBs by broadening the

circumstances in which market participants may find such Orders to be useful. With the

proposed changes, market participants will be more likely to determine that the benefits

of entering M-ELOs and M-ELO+CBs outweigh the risks of doing so.

The proposed change will not place a burden on competition among market

venues, as any market may adopt an order type that operates similarly to a M-ELO or a

M-ELO+CB with Dynamic M-ELO Holding Periods.

5.   <u>Self-Regulatory Organization's Statement on Comments on the Proposed Rule
        Change Received from Members, Participants, or Others</u>

No written comments were either solicited or received.

6.   <u>Extension of Time Period for Commission Action</u>

The Exchange does not consent to an extension of the time period for

Commission action.

EXHIBIT 1

SECURITIES AND EXCHANGE COMMISSION
(Release No.   ; File No. SR-NASDAQ-2022-079)

July__, 2023

Self-Regulatory Organizations; The Nasdaq Stock Market LLC; Notice of Filing of
Proposed Rule Change to Amend Rules 4702(b)(14) and (b)(15) of the Exchange's
Rulebook

       Pursuant to Section 19(b)(1) of the Securities Exchange Act of 1934 ("Act")[1], and

Rule 19b-4 thereunder,[2] notice is hereby given that on July 18, 2023, The Nasdaq Stock

Market LLC ("Nasdaq" or "Exchange") filed with the Securities and Exchange

Commission ("SEC" or "Commission") the proposed rule change as described in Items I,

II, and III, below, which Items have been prepared by the Exchange. The Commission is

publishing this notice to solicit comments on the proposed rule change from interested

persons.

I.   <u>Self-Regulatory Organization's Statement of the Terms of Substance of the
Proposed Rule Change</u>

       The Exchange proposes to amend Rules 4702(b)(14) and (b)(15) of the

Exchange's Rulebook to replace the static holding period requirements for Midpoint

Extended Life Orders and Midpoint Extended Life Orders Plus Continuous Book with

dynamic holding periods. This Amendment No. 2 supersedes the original filing and

Amendment No. 1[3] in their entireties.

The text of the proposed rule change is available on the Exchange's Website at

https://listingcenter.nasdaq.com/rulebook/nasdaq/rules, at the principal office of the

Exchange, and at the Commission's Public Reference Room.

II.   Self-Regulatory Organization's Statement of the Purpose of, and Statutory Basis
       for, the Proposed Rule Change

In its filing with the Commission, the Exchange included statements concerning

the purpose of and basis for the proposed rule change and discussed any comments it

received on the proposed rule change. The text of these statements may be examined at

the places specified in Item IV below. The Exchange has prepared summaries, set forth

in sections A, B, and C below, of the most significant aspects of such statements.

       A.   Self-Regulatory Organization's Statement of the Purpose of, and Statutory
             Basis for, the Proposed Rule Change

             1.   Purpose

The Exchange proposes to amend Rules 4702(b)(14) and (15) of the Exchange's

Rulebook to replace the static 10 millisecond holding period requirements for its

Midpoint Extended Life Order ("M-ELO") and Midpoint Extended Life Order Plus

Continuous Book ("M-ELO+CB") Order Types with dynamic holding periods

("Dynamic M-ELO and M-ELO+CB" or collectively, "Dynamic M-ELO").

Background

In 2018, the Exchange introduced the M-ELO, which is a Non-Displayed Order

priced at the Midpoint between the National Best Bid and Offer ("NBBO") and which is

eligible for execution only against other eligible M-ELOs and only after a minimum of

one-half second passes from the time that the System accepts the order (the "Holding

Period").[4] In 2019, the Exchange introduced the M-ELO+CB, which closely resembles the M-ELO, except that a M-ELO+CB may execute at the midpoint of the NBBO, not only against other eligible M-ELOs (and M-ELO+CBs), but also against Non-Displayed Orders with Midpoint Pegging and Midpoint Peg Post-Only Orders ("Midpoint Orders") that rest on the Continuous Book for at least one-half second and have Trade Now enabled.[5]

When the Exchange designed M-ELO, it originally set the length of the Holding Period at one-half second because it determined that this time period would be sufficient to ensure that likeminded investors would interact only with each other, and with minimal market impacts. The Exchange believed that the longer length of the M-ELO Holding Period and its simplicity in design would provide greater protection for participants than they could achieve through competing delay mechanisms.

In 2020, however, the Exchange shortened the length of the Holding Period to 10 milliseconds.[6] The Exchange did so after studying two years of actual use and performance of M-ELOs, as well as customer feedback. That is, the Exchange came to understand that, while users of M-ELO and M-ELO+CB are less concerned with achieving rapid executions of their Orders than are other participants, they are not indifferent about the length of time in which their M-ELOs and M-ELO+CBs must wait before they are eligible for execution. Indeed, participants informed the Exchange that in

[4]   See Securities Exchange Act Release No. 34-82825 (March 7, 2018), 83 FR 10937 (March 13, 2018) (SR-NASDAQ-2017-074) ("M-ELO Approval Order").

[5]   See Securities Exchange Act Release No. 34-86938 (September 11, 2019), 84 FR 48978 (September 17, 2019) (SR-NASDAQ-2019-048) ("M-ELO+CB Approval Order").

[6]   See Securities Exchange Act Release No. 34-88743 (April 24, 2020), 85 FR 24068 (April 30, 2020) (SR-NASDAQ-2020-011) ("M-ELO Timer Approval Order").

certain circumstances, such as when they sought to trade symbols that on average had a

lower time-to-execution than a half-second, they were reticent to enter M-ELOs or M-

ELO+CBs. They indicated that the associated Holding Periods for these Order Types

were longer than necessary to achieve the desired protections and that, during the residual

portion of the Holding Periods, they risked losing out on favorable execution

opportunities that would otherwise be available to them had they placed a non-MELO

order.

Based upon this feedback, the Exchange studied the potential effects of reducing

the length of the Holding Periods for both M-ELOs and M-ELO+CBs (as well as for

Midpoint Orders that would execute against M-ELO+CBs). Ultimately, the Exchange

determined that it could reduce the Holding Periods to 10 milliseconds without

compromising the protective power that M-ELO and M-ELO+CB are intended to provide

to participants and investors.[7] Thus, the Exchange determined that shortening the

Holding Periods to 10 milliseconds for M-ELOs and M-ELO+CBs would increase the

efficacy of the mechanism while not undermining the power of those Order Types to

fulfill their underlying purpose of minimizing market impacts. At the same time, the

Exchange determined that a reduction in the Holding Periods to 10 milliseconds would

---

[7]   The Exchange examined each of its historical M-ELO executions to determine at what Midpoints
       of the NBBO the M-ELOs would have executed if their Holding Periods had been shorter than
       one-half second (500 milliseconds). After examining the historical effects of shorter Holding
       Periods of between 10 milliseconds and 400 milliseconds, the Exchange determined that a
       reduction of the M-ELO Holding Period to as short as 10 milliseconds would have caused an
       average impact on mark-outs of only 0.10 basis points (across all symbols). In other words,
       compared to the execution price of an average M-ELO with a one-half second Holding Period, the
       Exchange found that a M-ELO with a 10 millisecond Holding Period would have had an average
       post-execution impact that was only a tenth of a basis point per share – a difference in protective
       effect that is immaterial. See Nasdaq, "The Midpoint Extended Life Order (M-ELO); M-ELO
       Holding Period," available at https://www.nasdaq.com/articles/the-midpoint-extended-life-order-
       m-elo%3A-m-elo-holding-period-2020-02-13 (analyzing effects of shortened Holding Periods on
       M-ELO performance).

dramatically add to the circumstances in which M-ELOs and M-ELO+CBs would be useful to participants. In its M-ELO Timer Approval Order, the Commission agreed with the Exchange:

The Commission notes that, with the proposed ten-millisecond Holding Period and Resting Period, M-ELOs and M-ELO+CBs would continue to be optional order types that are available to investors with longer investment time horizons, including institutional investors. The Commission also believes that the proposal could make M-ELOs and M-ELO+CBs more attractive for securities that on average have a time-to-execution of less than one-half second and, for investors who currently do not use M-ELOs and M-ELO+CBs for these securities, provide optional order types that could enhance their ability to participate effectively on the Exchange. The Commission notes that, if market participants determine that the proposal would make M-ELOs and M-ELO+CBs less attractive for their particular investment objectives, such market participants may elect to reduce or eliminate their use of these optional order types. Moreover, as noted above, the Exchange will continue to conduct real-time surveillance to monitor the use of M-ELOs and M-ELO+CBs to ensure that such usage remains appropriately tied to the intent of the order types. If, as a result of such surveillance, the Exchange determines that the shortened Holding Period does not serve its intended purpose or adversely impacts market quality, the Exchange would seek to make further recalibrations.[8]

For similar reasons and with even better potential results for participants, the Exchange now proposes to further refine the length of the Holding Periods for M-ELOs

---

[8]   M-ELO Timer Approval Order, <u>supra</u>, at 85 FR 24069.

and M-ELO+CBs, this time through the application of innovative and patent pending machine learning technology.

Dynamic M-ELO

After receiving feedback from participants that even 10 millisecond Holding Periods for M-ELO and M-ELO+CB may, at times, exceed what is necessary to accomplish the underlying intent of these Order Types, the Exchange began to experiment with making further refinements to the duration of the Holding Periods. Ultimately, the Exchange concluded that shorter Holding Periods could achieve the same, if not better results for participants in terms of mark-outs, but not in all circumstances. That is, where prices of the underlying securities are stable, and not subject to imminent unfavorable changes, M-ELOs and M-ELO+CBs face lower risks of confronting spread-crossing orders, such that shorter Holding Periods could suffice to protect M-ELOs and M-ELO+CB from such orders. In periods of heightened price volatility, however, M-ELOs and M-ELO+CBs also face heightened risks, such that longer Holding Periods would continue to be beneficial in protecting M-ELOs and M-ELO+CBs from such risks. Thus, the Exchange determined that another across-the-board reduction of the static 10 millisecond Holding Periods would be sub-optimal because it could impact the performance of the M-ELO and M-ELO+CB Order Types during periods of heightened volatility.

In light of these observations, the Exchange tasked its artificial intelligence and machine learning laboratory (the "AI Core Development Group") to explore whether it could employ these innovative technologies to optimize the length of M-ELO and M-ELO+CB Holding Periods during various states of price volatility, and then to vary the

lengths of the Holding Periods dynamically during the lifecycles of M-ELOs and M-ELO+CBs, with the objectives of improving the performance of these Order Types while also further reducing opportunity costs.

As the Exchange explains in greater depth in the attached white paper, [9] the AI Core Development Group proceeded to develop an artificial intelligence-based timer control system that will achieve these objectives. [10] The AI Core Development Group did so by using reinforcement learning techniques – machine learning paradigms which develop optimal solutions to problems over time by taking actions to solve them, generating feedback on the results of such actions, applying that feedback to direct and improve the next round of solutions, and then repeating the feedback loop until the paradigm achieves optimized solutions.

In this instance, the AI Core Development Group applied reinforcement learning techniques to a simulation of the M-ELO Book that it constructed using a representative data set from the first quarter of 2022 (the "Training Period"). The Training Period data consisted of 380 out of the 6,257 symbols on the M-ELO Book (accounting for approximately 67 percent of M-ELO volume). The symbols chosen reflect both actively-traded and thinly-traded securities, and both low-priced and high-priced securities.

---

[9]   See Diana Kafkes et al., "Applying Artificial Intelligence & Reinforcement Learning Methods Towards Improving Execution Outcomes," SSRN, October 19, 2022, available at https://papers.ssrn.com/sol3/papers.cfm?abstract_id=4243985 (attached hereto without modification from the prior version as Exhibit 3(a)) (the "White Paper").

[10]   Although the AI Core Development Group acknowledges that an optimal Holding Period would update with every incoming order, it determined that training a reinforcement learning model on every order would be too difficult to program and too difficult to implement given the nanosecond latency requirements of the Exchange. The Group then investigated more feasible update cadences and determined the point at which optimal outcomes were best balanced with the level of programming and implementation difficulty to be between 15 and 30 second updates. Ultimately, the Group chose a 30 second update cadence to give the model the greatest opportunity to learn between potential actions.

The AI Core Development Group then developed a machine learning model and applied it to the Training Period data. The Group programmed the model to value the achievement of higher fill rates or lower mark-outs than that which occurred in a historical simulation of M-ELOs and M-ELO+CBs involving the Training Period data. [11] The Group then programmed the model to seek to achieve its goals by taking one of five possible actions with respect to the duration of the Holding Periods at 30 second intervals[12] for each symbol during each trading day of the Training Period. That is, at each 30 second internal, the model evaluated market conditions for each symbol over the prior 30 second period and either kept the Holding Periods the same, increased/decreased them by 0.25 milliseconds, or increased/decreased them by 0.50 milliseconds.[13]   After each decision-making round, the model utilized the results to inform its actions at the next 30 second increment.

In making its decisions, the model (again, drawing upon a combination of historical SIP and M-ELO-specific data) considered 142 categories of data points. [14]   A confluence of data points that correlated with an increase in volatility tended to cause the

---

[11]   As the White Paper explains, the Group developed a model to simulate activity on the Exchange involving M-ELOs and M-ELO+CBs during the Training Period. See White Paper, supra, at 10.

[12]   See id.

[13]   The AI Core Development Group experimented with a range of permissible Holding Period durations. Ultimately, it concluded that it could produce better outcomes for M-ELO and M-ELO+CB participants than the existing approach using Holding Periods as low as 0.25 milliseconds and as high as 2.5 milliseconds, under normal market conditions.

[14]   Nasdaq attaches a full list of these data elements (attached hereto as "Exhibit 3(b)"), along with an observation of the strength of the correlations that currently exist between changes to those data values and decisions the system makes to set the duration of Holding Periods at any given time. The Exchange notes that the version of this list attached to this Amendment No. 2 supersedes prior versions attached to prior versions of this filing. This version of the list includes expanded explanations of the terminology used therein. See also White Paper, supra, at 31, for a description of these features.

model to increase the durations of Holding Periods, including increases in the standard deviation of NBBO prices, the number of unique participants placing sell orders on M-ELO and M-ELO+CB, and the volume-weighted average of the NBBO spread. Conversely, a confluence of data points that correlated with greater price stability tended to cause the model to decrease the durations of Holding periods, such as an increase in the median and max number of shares per trade and the number of resting bids left in the M-ELO and M-ELO+CB Book.

The AI Core Development Team produced variations of its model that prioritized achievement of the lowest mark-outs, the highest fill rates, and a blend of these two objectives. [15] Through a process of learning and experimentation involving a combination of historical and simulated data, the AI Core Development Group settled on a Dynamic M-ELO model that achieved substantial simulated performance improvements for users of M-ELO and M-ELO+CB – both in terms of mark-outs and fill rates – as compared to the static 10 millisecond Holding Periods. As the White Paper explains in greater detail, Dynamic M-ELO yielded an average combined volume-weighted (simulated) improvement of 31.7 percent, including a 20.3 percent increase in

---

[15]   The AI Core Development Group also applied to the model a paradigm called "retraining" to combat the degradation of model performance that can otherwise occur as the reference data it uses for initial comparison becomes stale. Finally, the AI Core Development group added a stability protection mechanism to the model to provide maximum production to participants in the event that the model observes extraordinary levels of instability in the National Best Bid and Offer during the prior three seconds as compared to reference data. When the model detects such instability, it is programmed to increase the length of the Holding Period to 12 milliseconds for a period of 750 milliseconds.

fill rates and a 11.4 percent reduction in mark-outs. [16] The White Paper provides a more fulsome explanation of these improvements.[17]

Based upon these exciting results, the Exchange now proposes to amend Rule 4702(b)(14) and (15) to replace the static 10 millisecond timers applicable to M-ELO and M-ELO+CB with Dynamic M-ELO Holding Periods. Using the Exchange's "proprietary assessment of market conditions"[18] and patent pending technology, the Dynamic M-ELO system will evaluate and, as it deems necessary, adjust the length of the Holding Periods for each symbol comprising M-ELOs and M-ELO+CBs (and Midpoint Orders on the Continuous Book that opt to interact with M-ELO+CBs after resting on the Book) every 30 seconds throughout the Market Hours (each such 30 second interval, a "Change Event"). In so doing, Dynamic M-ELO will help participants to achieve a more optimized blend of the underlying purposes of the M-ELO and M-ELO+CB Order Types: protection against adverse selection (low mark-outs) without sacrificing opportunities to achieve high-quality executions (high fill rates).

---

[16]   See White Paper, supra, at 22.

[17]   See id.

[18]   As set forth in the proposed rule text, the phrase "proprietary assessment of market conditions" refers to the Exchange's evaluation of prevailing market conditions for a given symbol using an algorithm programmed to set a Holding Period duration which, at each Change Event, achieves an optimal blend of two objectives: maximization of M-ELO fill rates; and minimization of M-ELO mark-out rates. As the rule text states and as is discussed below, the algorithm ingests and analyzes 142 data points, which the Exchange identifies and describes in Exhibit 3b hereto. The Exchange derives these data from a combination of public data and M-ELO data feeds. Furthermore, the Exchange conducts weekly re-trainings of the algorithm, outside of Market Hours, to improve its performance relative to the immediately preceding period (in terms of the two aforementioned objectives). The Exchange deploys a retrained version of the algorithm only if it determines that doing so will, in fact, improve its performance relative to the immediately preceding period. The Exchange provides further information about the algorithm and the retraining process in a White Paper attached hereto as Exhibit 3a.

A proposed M-ELO or M-ELO+CB with a Dynamic Holding Period will operate as follows. At the outset of Market Hours (approximately 9:30:00 AM), the Exchange will impose initial Holding Periods of 1.25 milliseconds for M-ELOs and M-ELO+CBs in all symbols. Thereafter, Holding Periods for a given symbol will become eligible to change dynamically from the initial duration beginning at 9:30:30AM and then at 30 second intervals thereafter during Market Hours. The Exchange will then apply to the M-ELO or M-ELO+CB Order a Holding Period that is of the duration that prevailed at the time of entry. For example, if participant A enters a M-ELO for symbol XYZ at 9:30:25 AM, then Holding Period for that M-ELO will be 1.25 milliseconds. If at 9:30:30:00 AM, the System decides to lower the duration of the Holding Period by 0.50 milliseconds, and then participant B enters a M-ELO for symbol XYZ at 9:30:45 AM, then the System will assign a 0.75 millisecond Holding Period to participant B's M-ELO. To be clear, the System will determine Dynamic M-ELO Holding Periods independently for M-ELOs and M-ELO+CBs in each symbol.

During normal market conditions, the range of potential Holding Period durations for M-ELOs and M-ELO+CBs will be between 0.25 – 2.50 milliseconds, with the Holding Period duration being eligible to change by increments of either 0.25 or 0.50 milliseconds at each Change Event. Thus, if the Holding Period for a M-ELO in symbol XYZ is set at 0.75 milliseconds at 2:22:11 PM, and at 2:22:41 PM, the System determines to increase the duration of the Holding Period, it may do so only by 0.25 or 0.50 milliseconds during that event.

When a Change Event occurs, and the System determines to adjust the duration of a Holding Period for a symbol, that adjustment will apply, not only to all M-ELOs and

M-ELO+CBs for that symbol entered within the 30 second period after the Change Event

occurs, but also to M-ELOs and M-ELO+CBs entered prior to the Change Event with

unexpired Holding Periods (with applicability retroactive to the time of Order

acceptance). Thus, if a participant enters a M-ELO in symbol XYZ at 1:14:299 PM, and

the prevailing Holding Period applicable to that M-ELO is 2 milliseconds, and at 1:14:30

PM, the System modifies the Holding Period to be 1.5 milliseconds, then the M-ELO will

become eligible to execute at 1:14:3005 P.M. This is the case because the M-ELO will

have already expended 1 millisecond of its Holding Period as of the time of the Change

Event; thereafter, the M-ELO will need to rest only another 0.5 milliseconds to become

eligible to execute under the new 1.5 millisecond Holding Period (as measured from

1:14:299 PM). This last feature ensures that the M-ELO Book maintains time priority

among M-ELOs and M-ELO+CBs in a dynamic environment. That is, it ensures that no

M-ELO or M-ELO+CB with an unexpired Holding Period at the time of a Change Event

will end up becoming eligible to execute later than a M-ELO entered after the Change

Event which has a shorter Holding Period applicable to it.

If at any time, the System detects extraordinary instability in a symbol, then the

System will activate a "stability protection mechanism" to provide an extra layer of

protection to M-ELO and M-ELO users from the heightened risks of adverse selection

that exists during such periods of instability.[19] The stability protection mechanism will

---

[19]   For purposes of this Rule, the System determines that "extraordinary instability" for a symbol
        exists through observations it makes following every change in the NBBO for that symbol that
        occurs during the trading day. When the NBBO changes, the System looks back at the prior three
        seconds of trading and measures the difference between the highest and the lowest NBBO
        midpoint values that occurred during that period, and then it compares that measurement to a
        threshold value for the symbol. The System concludes that extraordinary instability exists for a
        symbol if the measurement exceeds the threshold value.

override the prevailing Holding Periods for M-ELOs and M-ELO+CBs in a symbol experiencing extraordinary instability and immediately increase the duration of those Holding Periods to 12 milliseconds for a period of 750 milliseconds. The System may activate the stability protection mechanism even between Change Events. The System will evaluate, at each NBBO update, whether market conditions remain extraordinarily unstable and, if so, it will restart the 750 millisecond Stability Protected Period and maintain the 12 millisecond Holding Period until conditions stabilize. Once the System determines that market conditions have stabilized (i.e., all measurements for the symbol are at or below the threshold value throughout the duration of the prevailing Stability Protected Period), the System will revert the duration of the Holding Periods to that which prevailed as of the Change Event that occurred immediately prior to the activation of the stability protection mechanism or, if the stability protection mechanism was active when a Change Event occurred, to the duration selected at the immediately preceding Change Event. The System will then proceed to reevaluate the duration of the Holding Periods as per the regular schedule of Change Events.

The following is an illustration of the operation of the stability protection mechanism. At 11:10:04 AM, the prevailing Holding Period for M-ELOs in symbol XYZ is 1.5 milliseconds. At the same time, the NBBO for symbol XYZ updates. The System looks back at the prior three seconds of trading in symbol XYZ and finds that during that period, the highest observed NBBO midpoint was $10.05, and the lowest was $10.00, such that the difference between these two values is a range of $0.05. The

---

The threshold value for a symbol, in turn, is the difference between the highest and the lowest NBBO midpoint values for the symbol that, if applied to its trading activity during the prior trading day, would have caused the System to deem trading in the symbol to be extraordinarily unstable for as close to one percent of that day as possible.

System then looks back at trading behavior for symbol XYZ during the immediately preceding trading day. In doing so, the System calculates the value of the threshold that would have caused the symbol to be deemed extraordinarily unstable for one percent of the trading day; the System determines that this threshold value is a range of $0.03. The System then compares the $0.03 threshold to its measurement of the prior three seconds of NBBO changes ($0.05), and concludes that over these past three seconds, the symbol is extraordinarily unstable. Accordingly, the System activates the stability protection mechanism and the Holding Period for M-ELOs in symbol XYZ immediately increases to 12 milliseconds for a period of 750 milliseconds. However, 5 milliseconds after the Stability Protection Period commences, the NBBO updates again, thus prompting the System to repeat its assessment of the stability of the symbol in light of the update. This reassessment reveals that the symbol remains unstable, such that a new Stability Protection Period of 750 milliseconds begins at that time (overriding the pre-existing Period). Over the course of this new Stability Protection Period, the NBBO shifts two more times, but each of the ensuing reassessments indicate that the NBBO ranges for the symbol have fallen below the $0.03 threshold. The Stability Protection Period elapses 750 milliseconds after it began with the symbol remaining stable. Thus, the Holding Period reverts to 1.5 milliseconds.

If the Exchange halts trading in a symbol, then upon resumption of trading, any new M-ELO or M-ELO+CB in that symbol and any pending M-ELO or M-ELO+CB in that symbol with an unexpired Holding Period will be subject to a new 12 milliseconds Holding Period (running from the time when trading resumes) until the next scheduled Change Event, at which point the System may determine to adjust that Holding Period to

a duration within the range applicable under normal market conditions. [20] If, however, the System determines that extraordinary instability in the symbol exists, it will instead determine to activate the stability protection mechanism and maintain the duration of the Holding Period at 12 milliseconds for another 750 milliseconds. This design will help to ensure that M-ELOs and M-ELO+CBs receive added protection coming out of halt conditions.[21]

The Exchange notes that same dynamic process described above will also apply to and govern the time periods during which Midpoint Orders on the Continuous Book must rest before they will become eligible to interact with M-ELO+CBs (provided that participants have opted for their Midpoint Orders to interact with M-ELO+CBs). Thus, the same Holding Period duration that the System sets for a M-ELO+CB in a symbol during Regular Market Hours will also be the length of time that a Midpoint Order must rest on the Continuous Book must rest before it may interact with a M-ELO+CB.

Apart from these impacts of Dynamic Holding Periods, M-ELOs and M-ELO+CBs will continue to behave as they do now in all respects, and as set forth in Rules 4702(b)(14) and (15).

It is important to note that within the parameters discussed herein and in the White Paper, the Exchange will continue to re-train Dynamic M-ELO and M-ELO+CB

---

[20]   Prior to commencement of a new 12 millisecond Holding Period for a new or pending M-ELO or M-ELO+CB following a Halt, the System will first determine whether the M-ELO or M-ELO+CB is or remains eligible for execution. That is, the Holding Period will commence only if, upon commencement of trading following the Halt, the midpoint price for the Order is within the limit set by the participant. If not, the System will hold the Order until the midpoint falls within the limit set by the participant, at which time the 12 millisecond Holding Period will commence.

[21]   Also as a safeguard, the System will apply a default Holding Period of 12 milliseconds to a M-ELO or M-ELO+CB if ever it fails to receive a signal during a Change Event as to whether the System should adjust or maintain the duration of the prevailing Holding Period. The System will continue to apply the default 12 millisecond Holding Period until the next Change Event where the signal is restored and the System is able to act dynamically again.

on a weekly basis (outside of market hours) so that the model will continue to learn from and act upon the basis of more recent SIP and M-ELO book data sets, and further improve its performance over time. The retraining process should not result in dramatic or unpredictable changes to the behavior of Dynamic M-ELO. The retraining process will not retrain the model from scratch each week; rather, it will retain the model's existing data inputs, knowledge base, and objectives – all without alteration. Retraining will result in new behaviors only as needed to address new scenarios that the model did not confront previously, and even then, only in a manner designed to further optimize outcomes, i.e., reduce mark-outs or increase fill rates. If the System assesses that a retrained model would be worse than the existing model in achieving its objectives, then the System will continue to use the existing model and discard the retrained model. This retraining process is a standard and accepted practice for use of deep learning models; it helps to ensure that deep learning models not only work well, but that they continue to work well in dynamic circumstances. [22]

The Exchange will not modify the underlying structure of Dynamic M-ELO and M-ELO+CB without first obtaining the Commission's approval to do so, including modifications to the data elements the model considers in making decisions about Holding Period durations, the conditions under which the model may adjust the duration of Holding Periods, the frequency with which the model my adjust the Holding Periods, the range of Holding Period durations available to M-ELOs and M-ELO+CBs, the increments by which Holding Periods may change at any given Change Event, and the

---

[22]   During periods where the model is not undergoing retraining, the System will behave predictably
         from day to day, such that its decisions when presented with given set of facts and circumstances
         in a given security on day 1 should be the same as they would be on day 2.

procedures for triggering, maintaining, and ending 12 millisecond Holding Periods during times of extraordinary instability.[23] Although the Exchange will seek Commission approval prior to changing any of the data elements that the model considers, the Exchange will not seek Commission approval prior to retraining the model to adjust the weighting it applies to those data elements.

To aid investors in understanding and evaluating Dynamic M-ELO, Nasdaq will continue to publish weekly and monthly transparency statistics on Nasdaqtrader.com, as it does now, about the performance of its M-ELOs and M-ELO+CBs, including statistics listing the weekly numbers of shares and trades in M-ELOs by symbol, weekly aggregated M-ELO share and trade data, and monthly aggregated block data.[24] Nasdaq also will continue to disclose monthly data on Nasdaq.com, as it does now (the M-ELO Monthly Report), about M-ELO and M-ELO+CB mark-outs (quote stability by time horizon) and fill rates. [25] Moreover, Nasdaq will add statistics to the M-ELO Monthly Report about how frequently, on average, the System changes Holding Period durations for the top decile, median, and bottom decile of symbols, as measured by monthly M-ELO and M-ELO+CB trading volumes. Nasdaq will retain copies of each historical iteration of its models as part of its books and records, and make them available to the

---

[23]   In addition to the proposed changes described above, the Exchange proposes to delete an extraneous reference in Rule 4702(b)(15) to M-ELO+CB being eligible to execute against a Midpoint Order on the Continuous Book if the Continuous Book order has the "Midpoint" Trade Now Attribute enabled. In a prior filing, the Exchange folded the concept of "Midpoint Trade Now" into the general "Trade Now" Attribute. See Securities Exchange Act Release No. 34-92180 (June 15, 2021), 86 FR 33420 (June 24, 2021)(SR-NASDAQ-2021-044).

[24]   See http://www.nasdaqtrader.com/Trader.aspx?id=MELOSymbolData.

[25]   See, e.g., https://www.nasdaq.com/docs/M-ELO-Monthly-Report. Nasdaq understands that current users of M-ELO and M-ELO independently monitor the performance of these Order Types. Nasdaq often receives feedback from such users about M-ELO and M-ELO+CB performance, which Nasdaq then factors into decisions about improvements and enhancements. Nasdaq expects that this feedback loop will continue after implementation of Dynamic M-ELO.

Commission upon request, should it wish to examine them to understand how the model changes over time. Furthermore, Nasdaq will publish an equity trader alert in advance of deploying a retrained version of Dynamic M-ELO whenever Nasdaq has reason to anticipate that the retrained version will produce results that differ materially from the prior version, i.e., a projected change in mark-outs or fill-rates of 10% or more in either direction.

The Exchange acknowledges that systems necessary to implement Dynamic MELO, including the systems proposed that include model development and retraining processes, are "SCI Systems" within the meaning of Regulation Systems Compliance and Integrity ("Reg. SCI"), [26] and that the Exchange, as an SCI Entity, remains responsible for compliance with all requirements of Reg. SCI, including, without limitation, to have policies and procedures reasonably designed to ensure that its SCI Systems operate in a manner that complies with the Act and the rules and regulations thereunder and Exchange's rules and governing documents, among them a plan for assessments of the functionality of SCI Systems designed to detect systems compliance issues, including by responsible SCI personnel and by personnel familiar with applicable provisions of the Act and the rules and regulations thereunder and Exchange's rules and governing documents.

---

[26]   17 CFR 242.1000 et seq. As set forth in Reg. SCI, the term "SCI Systems" means "means all computer, network, electronic, technical, automated, or similar systems of, or operated by or on behalf of, an SCI entity that, with respect to securities, directly support trading, clearance and settlement, order routing, market data, market regulation, or market surveillance." Id. at 242.1000. An "SCI Entity" means "an SCI self-regulatory organization, SCI alternative trading system, plan processor, exempt clearing agency subject to ARP, or SCI competing consolidator." Id.

Implementation

The Exchange intends to make the proposed change effective for M-ELOs and M-ELO+CBs in the Second or Third Quarter of 2023, but that time frame is subject to change. The Exchange will publish a Trader Alert in advance of making the proposed change effective.

2.   Statutory Basis

The Exchange believes that its proposal is consistent with Section 6(b) of the Act,[27] in general, and furthers the objectives of Section 6(b)(5) of the Act,[28] in particular, in that it is designed to promote just and equitable principles of trade, to remove impediments to and perfect the mechanism of a free and open market and a national market system, and, in general to protect investors and the public interest, by allowing for more widespread use of M-ELOs and M-ELO+CBs.

When the Commission approved the M-ELO and the M-ELO+CB, it determined that these Order Types are consistent with the Act because they "could create additional and more efficient trading opportunities on the Exchange for investors with longer investment time horizons, including institutional investors, and could provide these investors with an ability to limit the information leakage and the market impact that could result from their orders."[29] Nothing about the Exchange's proposal should cause the Commission to revisit or rethink this determination. Indeed, the proposal will not alter

[27]   15 U.S.C. 78f(b).

[28]   15 U.S.C. 78f(b)(5).

[29]   M-ELO Approval Order, supra 83 FR at 10938–39; M-ELO+CB Approval Order, supra, 84 FR at 48980.

the fundamental design of these Order Types, the manner in which they operate, or their effects.

Even with Dynamic M-ELO Holding Periods, M-ELOs and M-ELO+CBs will continue to provide their users with protection against information leakage and adverse selection – and they will do so at levels which are substantially undiminished from that which they provide now.[30]

At the same time, however, the proposal will benefit market participants and investors by reducing the opportunity costs of utilizing M-ELOs and M-ELO+CBs. The proposal, in other words, will re-calibrate the lengths of the Holding Periods so that M-ELOs and M-ELO+CBs will operate in the "Goldilocks" zone – their Holding Periods will not be so short as to render them unable to provide meaningful protections against information leakage and adverse selection, but the Holding Periods also will not be too long so as to cause participants and investors to miss out on favorable execution opportunities. Nasdaq believes the proposal will render M-ELOs and M-ELO+CBs more useful and attractive to market participants and investors, and this increased utility and attractiveness, in turn, will spur an increase in M-ELO and M-ELO+CB use cases on the Exchange, both from new and existing users of M-ELOs and M-ELO+CBs. Ultimately, the proposal should enhance market quality by increasing opportunities for midpoint executions on the Exchange.

As Nasdaq explained above, the Proposal will operate within strict, well-defined, and transparent parameters. Although it will undergo weekly retraining (outside of

---

[30]   See note 6, supra.

market hours), [31] such retraining will aim to improve the performance of the model in

achieving its twin objectives; retraining will not alter the inputs, objectives, or basic

design parameters of Dynamic M-ELO without prior Commission approval. [32]

Moreover, the Exchange will not deploy a retrained model if it fails to achieve

performance improvements. To aid investors in evaluating Dynamic M-ELO, the

Exchange will publish statistics about its performance, including as to mark-outs and fill

rates, as well as statistics about how frequently the System changes Holding Period

durations. To further facilitate accountability, the Exchange will retain each historical

iteration of its model as part of its books and records, and make such information

available to the Commission, upon request. The Exchange will also publish equity trader

alerts whenever retraining will result in a performance change of 10% or more.

Nasdaq notes that the twin objectives it prescribes for the model involve the

absolute values of mark-outs and fill rates; they are not designed to further the

performance of any participant or any category of participant.   Furthermore, Nasdaq

performed internal tests of its AI model to detect indications of harmful bias in its

performance results, and such tests concluded that no such indications exist. That is, the

Exchange reviewed the impact on fill rates and mark-outs of Dynamic M-ELO, as

compared to the "static" M-ELO, for those firms that accounted for more than 95% of M-

---

[31]   To be clear, performance statistics for Dynamic M-ELO cited herein and in the White Paper are
         based upon data derived from weekly, not daily retrainings.

[32]   As discussed above, Nasdaq will not seek Commission approval prior to allowing the model, as
         part of its re-training process, to vary the weighting of the data elements it ingests. Nasdaq
         believes this is appropriate because such variance will only occur to the extent that it will improve
         the model's performance with respect to pre-defined objectives. Nasdaq will alert traders if the
         retraining process would result in substantial performance changes, and it will also publish
         statistics to help participants to assess performance themselves. Moreover, Nasdaq will retain
         historical iterations of its models for the Commission's review, should it wish to examine how
         these models have changed over time.

ELO activity on the Exchange during Q1 2022.[33] The Exchange analyzed results both in

an absolute and a relative sense. Testing revealed that all participants experienced at

least some improvements in fill rates and mark-outs when using Dynamic M-ELO versus

static M-ELO, with the volume-weighted average improvement being aligned with the

results expressed in the White Paper. We detected no material variations that might

suggest that a particular participant or category of participant (i.e., nature of firm; size of

firm) benefitted from Dynamic M-ELO functionality to an extent that was unreasonably

disproportionate to the benefits that other participants experienced. Thus, Nasdaq

believes the model is objective, is designed to, and does avoid bias and discrimination. [34]

The Exchange notes that use of Dynamic M-ELOs and M-ELO+CBs remains

voluntary for all market participants. Accordingly, if any market participant feels that the

dynamic Holding Periods are still too long or too short or because competing venues

offer more attractive delay mechanisms, then the participants are free to pursue other

trading strategies or utilize other trading venues. They need not utilize Dynamic M-

ELOs or M-ELO+CBs.

Furthermore, the design of Dynamic-MELO would constitute an "established,

non-discretionary" method that is consistent with the definition of an exchange, as set

---

[33]   Beyond this grouping of participants, the activity levels of other individual M-ELO participants
         were so small as to be insignificant. In many cases, these participants entered only a handful of
         M-ELOs during the study period. As such, the Exchange believes it is reasonable to exclude such
         participants from its analysis to avoid their data distorting the results.

[34]   The Exchange will review its AI model periodically to affirm that it continues to perform in
         accordance with the Exchange's rules and has not introduced any harmful bias in favor of or
         against any participant or category of participants.

forth in SEC Rule 3b-16.[35] The Commission stated as follows when it adopted Rule 3b-

16:

> A system uses established non-discretionary methods either by providing a
> trading facility or by setting rules governing trading among subscribers. The
> Commission intends for "established, non-discretionary methods" to include any
> methods that dictate the terms of trading among the multiple buyers and sellers
> entering orders into the system. Such methods include those that set procedures
> or priorities under which open terms of a trade may be determined. For example,
> traditional exchanges' rules of priority, parity, and precedence are "established
> non-discretionary methods," as are the trading algorithms of electronic systems.
> Similarly, systems that determine the trading price at some designated future date
> on the basis of pre-established criteria (such as the weighted average trading price
> for the security on the specified date in a specified market or markets) are using
> established, non-discretionary methods. [36]

Nothing in the Reg. ATS Adopting Release or in any of its illustrative examples suggests

that Dynamic M-ELO would constitute an exercise of discretionary behavior. Dynamic

M-ELO will handle and execute Orders according to published, pre-determined rules that

are disclosed to the public and which provide reasonable notice of how the Order Type

will behave.[37] To the extent that the design of the System permits variation in the

Holding Periods for such Orders, it does so by design. The range of potential variations,

the objectives that such variations are intended to achieve, and the factors that determine

---

[35]   See 17 CFR 240.3b-16(a)(2) ("(a) An organization, association, or group of persons shall be
considered to constitute, maintain, or provide 'a market place or facilities for bringing together
purchasers and sellers of securities or for otherwise performing with respect to securities the
functions commonly performed by a stock exchange,' as those terms are used in section 3(a)(1) of
the Act, (15 U.S.C. 78c(a)(1)), if such organization, association, or group of persons: (1) Brings
together the orders for securities of multiple buyers and sellers; and (2) Uses established, non-
discretionary methods (whether by providing a trading facility or by setting rules) under which
such orders interact with each other, and the buyers and sellers entering such orders agree to the
terms of a trade.").

[36]   See Securities Exchange Act Release No. 40760 (December 8, 1998), 63 FR 70844, 70850
(December 22, 1998).

[37]   See id. at 70900 ("an essential indication of the non-discretionary status of rules and procedures is
that those rules and procedures are communicated to the systems users'' and ''[t]hus, participants
have an expectation regarding the manner of execution—that is, if an order is entered, it will be
executed in accordance with those procedures and not at the discretion of a counterparty or
intermediary.").

when such variations may occur are also predetermined and set forth in the Exchange's

Rules or otherwise disclosed to the public. The mere fact that the System may apply

different weights over time to the factors it uses to determine whether and by how much

to vary a Holding Period does not mean that the System will act with discretion in the

same sense that a human being could be said to be exercise independent judgment when

deciding whether and how to handle an order.[38] Even when the System makes decisions

about changing the Holding Periods, the System will operate pursuant to a mathematical

algorithm from which it cannot deviate – an algorithm that is programmed to achieve pre-

defined and pre-disclosed objectives. [39]

---

[38]   Cf. id. at 70851 (explaining that a traditional block trading desk is an example of a system that does not use established, non-discretionary methods because the operators of such desks do not act according to fixed procedures known to their customers, but instead shop orders around for potential counterparties and make their own determinations as to whether and how to execute block orders, including by sometimes deciding to take a proprietary position in part of the block order).

[39]   See id. at 80755 (describing an example of a system that would be non-discretionary in nature: "System I permits participants to enter a range of ranked contingent buy and sell orders at which they are willing to trade securities. These orders are matched based on a mathematical algorithm whose priorities are designed to achieve the participants' objectives. System I does not display orders to any participants. System I is included under Rule 3b-16."); see also Securities Exchange Act Release No. 34-89686 (August 20, 2020), 85 FR 54438, at 54445, n.92 (September 1, 2020) (Order approving SR-IEX-2019-15) (rejecting argument that IEX's D-Limit order time is an exercise of discretion because "D-Limit orders will not allow IEX to exercise any discretion on any particular order by deviating from the CQI and D-Limit functionality, which is hardcoded in the IEX rulebook."; Securities Exchange Act Release No. 34-78101 (June 17, 2016), 81 FR 41141, at 41153(June 17, 2016) (Order approving IEX Form 1 and D-Peg Order Type) ("the Commission does not believe that the hardcoded conditionality of the IEX proposed ''discretionary'' peg order type provides IEX with actual discretion or the ability to exercise individualized judgment when executing an order. Rather, if IEX's fixed formula determines the quote to be stable, the discretionary peg order can execute up to the midpoint; if it does not deem the quote to be stable, then it will hold the order to its pegged price. As such, IEX would not exercise discretion over the routing and execution of a resting order"). Nasdaq does not believe that it is necessary to codify its mathematical formula for Dynamic M-ELO in its Rules because Nasdaq has disclosed sufficient information in its Rules and in its filing to inform the public as to the possible and expected behaviors associated with Dynamic M-ELO, as well as a means for the Commission and/or investors to verify whether Dynamic M-ELO is performing appropriately. Much as the Commission does not require an exchange to codify the source code it uses to effectuate other behaviors or actions that it explains in its Rules, including the behaviors of other complex Order Types, there is no basis to require codification of the Dynamic M-ELO formula in this instance.

The Exchange notes that it will continue to conduct real-time surveillance to monitor the use of M-ELOs and M-ELO+CBs to ensure that such usage remains appropriately tied to the intent of the Order Types. If, as a result of such surveillance, the Exchange determines that the Dynamic M-ELO Holding Periods do not serve their intended purposes, or adversely impact market quality, then the Exchange will seek to make further re-calibrations.

Nasdaq does not believe that the design of Dynamic M-ELO lends itself to potential manipulation by a single participant or a small group of participants because the System makes determinations regarding Holding Periods based upon prevailing market-wide conditions for a given symbol, rather than the behaviors of particular participants with respect to that symbol, or the activity of participants in M-ELOs involving that symbol.   Manipulation of the System also would be difficult to accomplish given the large number of variables that factor into the System's decisions to change Holding Periods during Change Events, as well as the different weighs that apply to each such factor, which as described above, the System may vary over time. Any benefits that a participant might derive from manipulating the duration of Holding Periods would likely be small and outweighed significantly by the difficulty and cost of affecting such manipulation. Nevertheless, the Exchange will surveil for indications of manipulation and act accordingly if it detects such indications.

B.   Self-Regulatory Organization's Statement on Burden on Competition

The Exchange does not believe that the proposed rule change will impose any burden on competition not necessary or appropriate in furtherance of the purposes of the Act. To the contrary, the Exchange believes that this proposal will promote the

competitiveness of the Exchange by rendering its M-ELO and M-ELO+CB Order Types more attractive to participants.

The Exchange adopted the M-ELO and M-ELO+CB as pro-competitive measures intended to increase participation on the Exchange by allowing certain market participants that may currently be underserved on regulated exchanges to compete based on elements other than speed. The proposed change continues to achieve this purpose. With Dynamic M-ELO Holding Periods, both M-ELOs and M-ELO+CBs will afford their users with a level of protection from information leakage and adverse selection that is better from what is achievable at present.[40] At the same time, the Dynamic Holding Periods will increase opportunities to interact with other like-minded investors with longer time horizons while also lowering the opportunity costs for participants that utilize M-ELOs and M-ELO+CBs, particularly for securities that trade within the "Goldilocks" zone. In sum, the proposed changes will not burden competition, but instead may promote competition for liquidity in M-ELOs and M-ELO+CBs by broadening the circumstances in which market participants may find such Orders to be useful. With the proposed changes, market participants will be more likely to determine that the benefits of entering M-ELOs and M-ELO+CBs outweigh the risks of doing so.

The proposed change will not place a burden on competition among market venues, as any market may adopt an order type that operates similarly to a M-ELO or a M-ELO+CB with Dynamic M-ELO Holding Periods.

C.   Self-Regulatory Organization's Statement on Comments on the Proposed Rule Change Received from Members, Participants, or Others

No written comments were either solicited or received.

---

[40]   See White Paper, supra.

III.   Date of Effectiveness of the Proposed Rule Change and Timing for Commission
         Action

Within 45 days of the date of publication of this notice in the Federal Register or

within such longer period (i) as the Commission may designate up to 90 days of such date

if it finds such longer period to be appropriate and publishes its reasons for so finding or

(ii) as to which the Exchange consents, the Commission shall: (a) by order approve or

disapprove such proposed rule change, or (b) institute proceedings to determine whether

the proposed rule change should be disapproved.

IV.   Solicitation of Comments

Interested persons are invited to submit written data, views and arguments

concerning the foregoing, including whether the proposed rule change is consistent with

the Act. Comments may be submitted by any of the following methods:

Electronic Comments:

- Use the Commission's internet comment form

     (https://www.sec.gov/rules/sro.shtml); or

- Send an email to rule-comments@sec.gov. Please include file number

     SR-NASDAQ-2022-079 on the subject line.

Paper Comments:

- Send paper comments in triplicate to Secretary, Securities and Exchange

     Commission, 100 F Street NE, Washington, DC 20549-1090.

All submissions should refer to file number SR-NASDAQ-2022-079. This file

number should be included on the subject line if email is used. To help the Commission

process and review your comments more efficiently, please use only one method. The

Commission will post all comments on the Commission's internet website

(https://www.sec.gov/rules/sro.shtml). Copies of the submission, all subsequent

amendments, all written statements with respect to the proposed rule change that are filed

with the Commission, and all written communications relating to the proposed rule

change between the Commission and any person, other than those that may be withheld

from the public in accordance with the provisions of 5 U.S.C. 552, will be available for

website viewing and printing in the Commission's Public Reference Room, 100 F Street

NE, Washington, DC 20549, on official business days between the hours of 10 a.m. and 3

p.m. Copies of the filing also will be available for inspection and copying at the principal

office of the Exchange. Do not include personal identifiable information in submissions;

you should submit only information that you wish to make available publicly. We may

redact in part or withhold entirely from publication submitted material that is obscene or

subject to copyright protection. All submissions should refer to file number SR-

NASDAQ-2022-079 and should be submitted on or before [INSERT DATE 21 DAYS

AFTER DATE OF PUBLICATION IN THE *FEDERAL REGISTER*].

For the Commission, by the Division of Trading and Markets, pursuant to

delegated authority.[41]

Sherry R. Haywood,

Assistant Secretary.

Applying Artificial Intelligence & Reinforcement Learning Methods Towards Improving Execution Outcomes

Diana Kafkes*, Josep Puig Ruiz*, Drew Rooks*, Douglas Hamilton*, and Michael O'Rourke*

Nasdaq Stock Exchange

October 10, 2022

1 Introduction

Capital markets are dynamic and always evolving. This constant evolution provides opportunities to enhance timer based solutions to improve execution outcomes and further mitigate adverse selection and volatility. This paper proposes the introduction of a dynamic model-based timer that can be applied to the Nasdaq Midpoint Extended Life Order (M-ELO).

The current M-ELO uses a holding period— a brief waiting timer applied to the queue on both sides— statically set at 10ms (10^{-3} s). This holding period achieves relatively favorable markout when trading institutional loads with respect to the continuous book, achieving the intended purpose of matching like-minded long-term investors. However, this occurs at some expense of fill rate given the differences in the dynamics of individual securities. Our research shows that the interplay between fill rate and markout is more nuanced than a simple trade-off, as previous literature indicates. Here we demonstrate that achieving both higher fill rate and lower markout

*diana.kafkes@nasdaq.com, josep.ruiz@nasdaq.com, drew.rooks@nasdaq.com, douglas.hamilton@nasdaq.com, michael.orourke@nasdaq.com

1

is possible through leveraging Artificial Intelligence (AI) towards achieving dynamically-improved timer execution.

Our Dynamic M-ELO system[1] leverages an AI control scheme known as reinforcement learning to evaluate the duration of the holding period timer based on local market conditions. Our research shows that applying a dynamic timer to MELO achieves an increase in fill rate of 20.3% and a simultaneous decrease in markout of 11.4% compared to the current static holding period. We believe that these results are indicative of the many improvements AI-enhanced mechanisms can bring to capital markets. Here we detail the development and results of our proposed timer-update model and advance its adoption as a step towards the future of dynamic market order types.
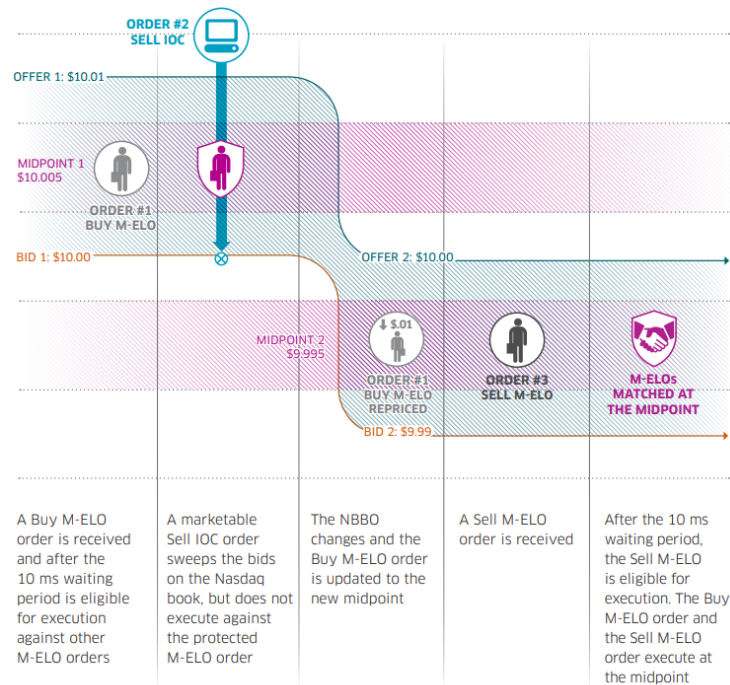

Figure 1: An example of a M-ELO trade.

---

[1] Our Dynamic M-ELO system is patent pending; we have filed several patent applications covering various aspects of it.

2   Assessing the State of the Current Static Holding Period

First, we present some details on how the current holding period used with M-ELO[2] functions in order to provide context for the improvement gains our system is able to make on the original.

The current static holding period market is designed to match like-minded longer-term investors on a broker-neutral exchange. When a M-ELO order is entered, it is held for a period of time before it becomes executable (Figure 1). This period of time depends both on the static holding period timer and a M-ELO order eligibility condition.

2.1   M-ELO Eligibility to Trade

Incoming M-ELO orders in the current implementation are assigned a static waiting timer of 10ms. This timer was updated from its earlier value of 500ms in May 2020.

This timer is only activated by a specific midpoint-crossing eligibility condition: the NBBO (National Best Bid and Offer) of the security or fund must have favorably crossed the price of the entered order. For buy orders, this means that the orders become eligible if the midpoint of the NBBO for that security is either at or lower than the bid price of the M-ELO order. Similarly, for sell orders, the midpoint of the NBBO must be either at or higher than the ask price of the M-ELO order in order to be eligible. As soon as an order becomes eligible by this criteria, it begins its waiting period of 10ms.

It is important to note that the waiting timer is not set off immediately when an order is entered, and to distinguish the two distinct waiting periods an order faces in the M-ELO queue: one before it is deemed eligible based on a midpoint-crossing condition and one that depends on the holding period timer assigned, in this case 10ms.

---

[2]Please note that the proposed system can be applied to both Nasdaq Midpoint Extended Life Order (M-ELO) and Nasdaq Midpoint Extended Life Order Plus Continuous Book (M-ELO+CB). For the sake of brevity in notation, and unless otherwise noted, we will henceforth refer to both M-ELO and M-ELO+CB as simply "M-ELO".

3
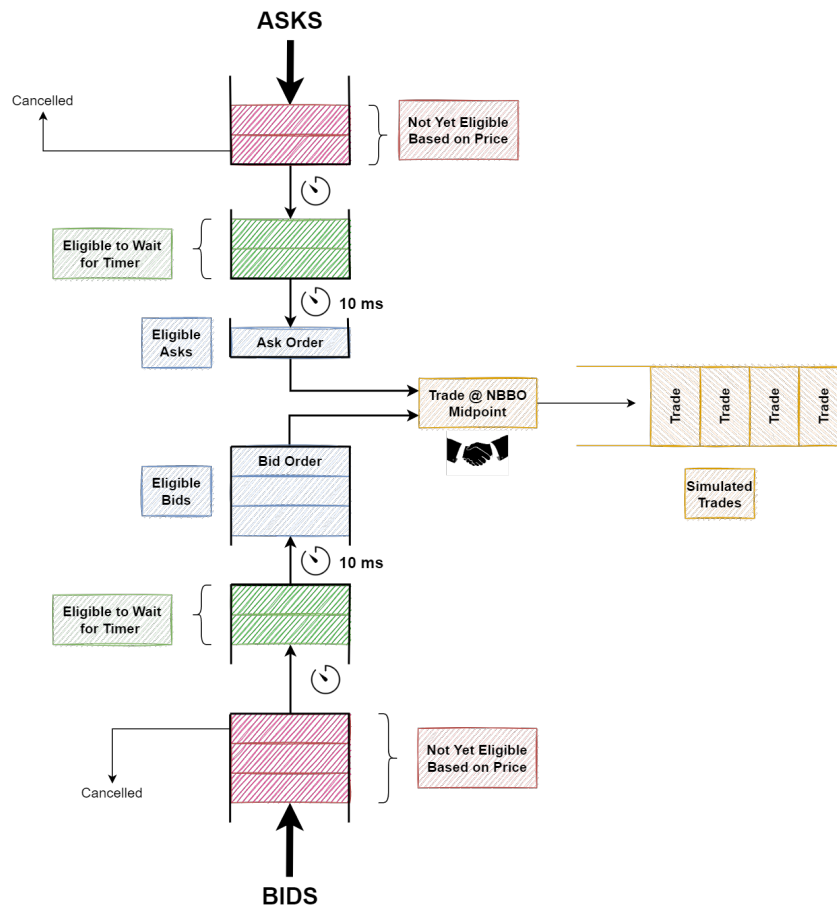

Figure 2: How Orders Become Eligible To Trade on M-ELO

2.2 Fill Rate-Markout Trade-off

While all orders are treated equally by the assignment of the same timer in the simplest notion of the word, certain trade-offs arise from the static timer's interactions with non-static market conditions that affect orders unequally.

2.2.1 Defining Fill Rate and Markout

In order to address these inefficiencies, we first must define two metrics that give us some notion for the underlying liquidity and execution quality of the market: fill rate and markout, respectively [5, 6, 7]. We will refer to these

4

metrics throughout this White Paper in order to evaluate the performance of the current M-ELO market as well as our proposed adjustment to it that achieves the best of both worlds: increased fill rates and decreased markout. We define fill rate for a period of time and markout by trade as follows:

$$\text{FR}_{\text{period}} = \frac{\text{Shares Traded}}{\text{Total Incoming Shares}} \tag{1}$$

$$\text{MO}_{\delta,\text{bps,trade}} = \left\{ \begin{array}{l} MO_{\delta,\text{bps,trade Buy}} = \left| \frac{-100*100(M_t - M_{t+\delta})}{M_{t+\delta}} \right| \\ MO_{\delta,\text{bps,trade Sell}} = \left| \frac{100*100(M_t - M_{t+\delta})}{M_{t+\delta}} \right| \end{array} \right. \tag{2}$$

where M_t is the midpoint of the NBBO at time t and δ_t denotes a specific time horizon.

Note here that the markout is always positive, i.e. it is defined as the absolute value of the price (dis)improvement for each side and counts as a penalty for any price movement within the time horizon. The negative sign inside the absolute value operator for the "Buy" markout component is not strictly needed, but we've decided to leave it in place to highlight the fact that generally price improvement for one side of a trade is met with price disimprovement for the other side of the same trade. Regardless, the goal is to minimize price deviation in *any* direction, hence the absolute value operator.

It's also worth noting that, while we considered many different time horizons in our research, here we will focus on discussing the specific case with $\delta_t = 1$ second (1s), i.e. the markout expressed in basis points (bps) one second after trading. Different time horizons yield similar results.

Lastly, note also that we are using a simplified aggregate shares formula for fill rate instead of fulfillment $\times$ hit rate. Using this alternative definition also yields similar results.

2.2.2 Static Timer vs. Non-Static Market Conditions

We propose here a solution that leverages AI to provide a bespoke intraday symbol-specific recommendation for the holding period at any given time, based on the specific conditions for that symbol. We find that by allowing for the holding period to change for each specific security and every 30 second interval we can further enhance the favorable outcomes that M-ELO participants already see.

5

We present a few simple examples to show how M-ELO currently operates and why it is effective. After that, we will demonstrate as well the additional value of having a changing holding period under certain situations.

We present first two examples that showcase the current behavior of M-ELO, and why it works well in providing favorable execution for like-minded parties, through Figures 3a and 3b. Two M-ELO orders, A and B, are placed, wait for the holding period of 10ms to elapse, and then become eligible to trade at the midpoint of the NBBO.

- Figure 3a depicts a situation in which the market conditions are very stable throughout. Under such circumstances, M-ELO allows for execution to occur, matching the two like-minded parties, and the outcome is satisfactory to both sides.

- Similarly, Figure 3b shows a situation in which market conditions get momentarily unstable, and price fluctuates significantly. Since the order that arrived later needs to wait as well for the holding period to elapse, the execution does not occur during this unstable moment, but rather occurs at a slightly later time, once the new price level is established. As a result, the later execution is favorable to both sides.

Now, we highlight how a changing holding period can further increase the performance of M-ELO. Order A is placed, waits for 10ms, and is now ready to trade, but there is no liquidity on the other side yet, so it rests. Moments later, a sell M-ELO order, Order B, is placed too. The conditions at this point in time are very stable for this symbol: if Order B was to trade immediately with Order A, the execution outcome would be favorable for both sides.

However, Order B needs to wait as well for the holding period to elapse. We explore two possible situations based on the duration of the holding period:

- With the static timer of 10ms, Order B needs to wait for 10ms. At some point, while waiting for the 10ms to elapse, market conditions worsen. Once the timer has elapsed, Order B becomes eligible to trade. Consequently, a trade occurs between Orders A & B at the midpoint of the NBBO. Due to the recent instability, the execution outcome is less favorable. This situation is depicted in Figure 4a.

6
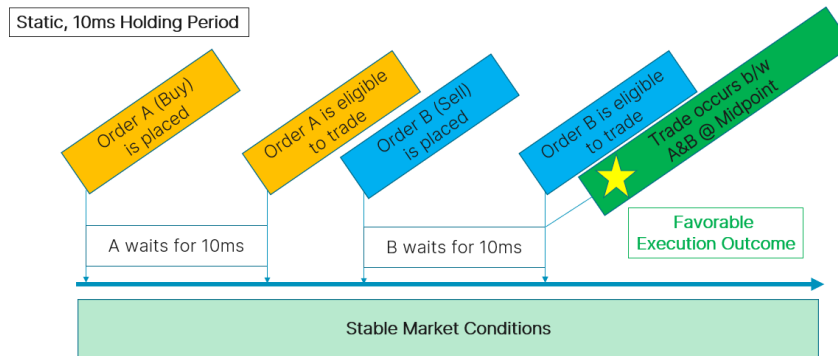

(a) M-ELO in normal market conditions.
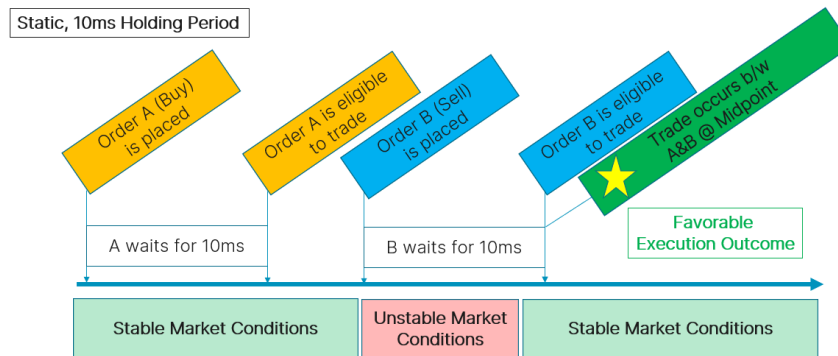

(b) M-ELO in unstable market conditions.

Figure 3: Example showing how current static M-ELO operates and how it effectively provides favorable execution outcomes that would have otherwise occurred in both normal and unstable market conditions.

- In contrast, assume a shorter dynamic timer, for example 2ms, and a stable market. The shorter dynamic allows A & B to trade sooner, which is a more favorable outcome for both parties during a stable period in the market. It is indeed a current market reality that execution algorithms brokers provide to asset managers and other institutions often need to rebalance liquidity across venues which may cause orders that could potentially match to miss each other due to a timer that is longer than it needs to be to provide the right level of protection. Fewer missed executions increases the efficacy of those broker algorithms and

7

therefore improves investor experience in M-ELO. Indeed, there are situations in which a changing holding period provides desirable outcomes, highlighting the need for the proposed solution. This situation is depicted in Figure 4b.
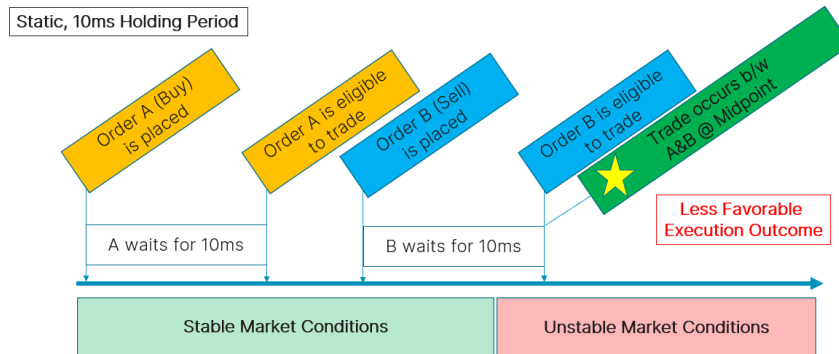

(a) Static timer might result in less favorable outcomes under specific circumstances.
(b) Shorter timer might result in more favorable outcomes under specific circumstances.

Figure 4: Example where a static timer might result in a less favorable execution outcome, showcasing the value of dynamically reducing the timer under specific circumstances.

Lastly, for the rare situation in which market conditions significantly deteriorate and a longer holding period might be desirable to shield against

8

volatility, the stability protection mechanism will be momentarily activated, increasing the holding period to a higher value for a short amount of time. This mechanism, which is described in more depth in Section 4.3, is depicted in Figure 5.
Figure 5: The stability protection mechanism acts as a safeguard against undesired execution outcomes driven by periods of high, unusual volatility. More details on this can be found in Section 4.3

9

3 Building an AI-Based Timer-Control System

Dynamic M-ELO is an AI-based control system that learns from watching market behavior and can dynamically adjust the holding period timer to improve client outcomes with respect to both liquidity and execution quality. The model evaluates changes to the timer between the range of .25 to 2.5ms by .25ms increments every 30 seconds (780 times per day) and includes stability protection enhancement (discussed at length in Section 4.3) that briefly overrides the timer to 12ms in the case of high volatility.

Here we discuss the methodology involved in the creation of Dynamic M-ELO, including an overview of reinforcement learning, how we built and validated a surrogate environment for our training process, and insight into our model development.

3.1 Reinforcement Learning

We framed our dynamic timer control solution as a reinforcement learning problem. We did this because we needed a way for our model to interact with and receive feedback from the trading system based on each timer chosen. Other machine learning approaches would have involved simulating a large or even intractably-large—depending on the frequency of timer updates chosen— number of timer-paths across our chosen learning period. This made reinforcement learning the clear choice.

Reinforcement learning is an AI paradigm in which a model ("agent") is trained to take the most optimal actions in an environment. This is achieved by the model taking random actions at first and receiving feedback— both positive and negative— in the form of a reward that is then used to tailor the model's future approach [3]. Overtime, the agent gradually switches from exploring its environment through random actions to exploiting what it has learned through these earlier actions [3]. The training of the model in this way involves a loop (Figure 6) that borrows heavily from the psychology of how we learn to walk or ride a bike— with all the falls, cuts, and scrapes included on the way to eventually achieving balance.

In a generic single iteration known as an episode: the agent takes an action and receives feedback from the environment in the form of both a reward and the next state from which it can take another action. Each time around the loop generates a (state, action, reward, next state) "experience" which is stored in what is known as the agent's memory buffer and accessed

10
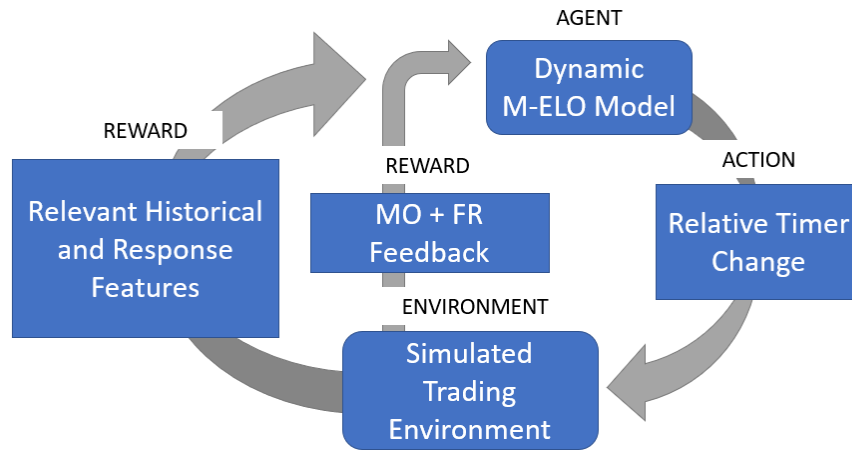

Figure 6: The Reinforcement Learning framework used to train Dynamic M-ELO.

for training [**3**].

Likewise, in our Dynamic M-ELO training process, we have a model (agent) select a relative timer change (action) that then impacts a simulated trading environment which provides feedback in the form of the next state and reward. In this case, the next state provided is the relevant historical and response features returned from the environment and the reward is a share-weighted linear combination of fill rate and markout, the proxies for liquidity and execution quality we discussed before in Equations 1 and 2:

$$\frac{\lambda}{\sum q_i} \sum_{i=1}^{T} q_i(\text{MO}_{\delta,\text{agent,bps}} - \text{MO}_{\delta,\text{synthetic@10,bps}}) + (1 - \lambda)(\text{FR}_{\text{agent}} - \text{FR}_{\text{sim@10}}) \tag{3}$$

where q_i is the number of shares traded in trade i, T is the total number of trades in a period, and λ is a weighting design factor. This can be interpreted as the marginal advantage the Dynamic M-ELO agent is able to achieve with respect to the 10ms M-ELO as represented in our simulated environment. For a comprehensive explanation of how the simulated environment at 10ms

11

corresponds with historical M-ELO data, please see Section 5.1.

3.2 Developing a Simulation of M-ELO with a Non-Static Holding Period

In order to train our agent, we first had to build a simulated M-ELO trading environment. Without it, the Dynamic M-ELO agent would not have had a safe place to interact with and learn from without causing undue damage. This is often done in reinforcement learning to ensure that the actual environment is not disturbed. Within this simulated trading environment, the agent is able to change the duration of the holding period timer and receive positive and negative feedback relating how the environment's internal state reacts to this timer change.

The simulation built mostly consists of the M-ELO order eligibility logic detailed in Section 2.1 wrapped around a matching engine that ingests historical and slightly modified data. This matching engine accepts orders, cancellations, and replacements and has the basic capability of matching buy/sell orders of the same symbol at the same price.

The reason why slightly modified data is needed as an input to the matching engine is that the simulation is built to show what the trading environment *would have been* like at timers other than 10ms. This timer change importantly affects user's cancellation behavior.

3.2.1 Simulating Cancellations

We defined a way to statistically model appropriate cancellation behavior at timers other than 10ms based on historical past behavior. For each order without historical cancellation after the 10ms holding period, we sample from a binomial distribution to figure out whether or not the order would have a chance of cancelling. This binomial distribution was fit using the likelihood of that user cancelling for each specific symbol at a given time of day. If the user in question did not historically cancel that symbol at that time of day, we used that user's overall probability of cancelling for that symbol in general.

If the results of the binomial draw were favorable for cancellation, we then sampled the time interval between when the order was placed and when the cancellation would occur from an exponential distribution. This exponential distribution's parameters were fit from past user historical cancellation

12

behavior for that symbol at that time of day. Similarly to the likelihood of cancelling calculation, missing values were filled in first by the user for that symbol, and then for that user in general.

3.2.2 Validating our Simulation
Figure 7: Validation of simulation against historical with and without simulated cancellation behavior. Results presented are a subset.

We ran our simulation forward at the 10ms timer to validate it. We received high RMSE values (averaging above .95, and all greater than .88) when plotting our resulting trades for specific symbols in comparison with the historical. The overall trend is that our simulation tends to undershoot the historical trades by a small amount. Performing this study at 10ms verified that we could replicate historical M-ELO activity with high fidelity and gave us high confidence that we could use this simulation to provide a reasonable estimate for the trading environment at different timers. Therefore, we could use the simulation as a training ground for our agent.

13

4 Model Development

Our timer-set agent is a deep neural network with multiple layers and over 35,000 parameters. It was trained following the DDQN (Double Deep Q-Network) training paradigm, where the agent's state-action value (Q-value) is approximated using a deep neural network [2].

4.1 Understanding DDQN

The Q-value provides some notion of the long-term value of a discrete sum of the agent's discounted actions [1]. To make this more concrete, the agent's actions will update the state it is in, sometimes in favorable ways and sometimes in nonfavorable ways. The favorable updates will increase the Q-value, and the nonfavorable actions will decrease the Q-value. These incremental updates are summed together for a discrete number of times around the RL Loop (Figure 6) with a nearsighted discount factor that makes Q-value updates that happened earlier in the chain decrease in impact as time goes by. Through many iterations of the training loop, the Q-value can be optimized.

The DDQN algorithm is a variant of the DQN algorithm, and involves initializing two identical models— a main and target network— and updating the target model's weights less frequently than the main model's [2]. While the main model goes around the loop and collects batches of (state, action, reward, next state) experiences in its memory buffer, the target model's parameter updates happen less frequently than the main model's for the sake of stability. This means that the target model's parameters cannot become over-adapted to one set of experiences, rendering it more stable than the main network which adapts itself to each set of sampled experiences. This lag is advantageous as the main model's parameters are periodically updated to be a weighted average of the main model and the more stable target model, ensuring it retains a middle ground of adaptation.

4.2 The Training Process

We trained our agent on data derived from our simulation operating between January 1, 2022 and April 1, 2022 (Q1)— a time period which we assessed to be representative in both duration and market behavior, including a range of relevant market volatility conditions. From this period of time, we used 380 symbols that represent a subset of the 6257 symbols that are actively

14

traded with M-ELO. This subset covers 67% of the current M-ELO volume and includes both tick- and nontick-constrained stocks.

Each trading day that the agent experiences consists of 380 (number of symbols) symbol-days. Each symbol-day is discretized into 30 second periods that our agent steps through, meaning there are (number of trading days) $*$ (number of tickers) $* (780 \times \frac{30 \text{ sec periods}}{\text{day}})$ episodes— times around the RL Loop— in our training process.

We restrict our agent to take 5 possible actions each 30 second period: it is able to change the timer by [-.5, -.25, 0, +.25, +.5] ms. It does this by evaluating the past 30 seconds of market conditions which are output from our simulation. This includes historically-based information such as features derived from the one- and five-day moving averaged M-ELO historical orders and trades, NBBO historical moments, the continuous book; as well as timer-dependent information such as the resultant fill rate, markout, and metrics derived from agent-made trades and simulated M-ELO activity.

There are 142 features in total, and they make up the state and next state part of the (state, action, reward, next state) experiences that the agent samples at the end of each calendar day to train from. For more technical details regarding the training process, including the pseudo-code, please see Appendix 7.

4.2.1 Motivating Allowable Timer Values

The optimal range of timers was chosen through substantial experimentation. First, we researched the lowest value the timer could take while retaining similar markout to those achieved by the original M-ELO during stable periods. We then found a timer that could effectively mitigate markout across periods of mild instability. For extremely unstable periods (which will be properly defined in Section 4.3), we chose 12ms as our stability protection timer since we found it to be the lowest value that achieves substantial gains over the current M-ELO during high volatility events.

Likewise, the 30 second update cadence was chosen by considering the difficulty of learning at different frequencies and our system's latency requirements. We assert that the theoretical best-possible timer would update with every incoming order. However, training a reinforcement learning agent on every order would be a difficult problem to generalize, resulting in a brittle model. Additionally, despite recent advances in fast electronics, this would be difficult to implement in real-time where nanosecond-latency is required. We

15
(a) Trade-off between training feasibility and potential upside gains, as a function of the frequency of timer update.
(b) Optimal frequency of timer update, based on the trade-off above.

Figure 8: Choosing the frequency of timer update.

16

investigated achievable update cadences and found that the point of marginal returns was between 15 and 30 second updates, and decided to go with 30 seconds to give our agent the best chance of learning generalizable actions (Figure 8).

4.2.2 Model Maintenance in Production

We can expect M-ELO environment market dynamics, like any other capital market dynamics, to evolve over time. These sorts of changes account for what is known in statistics as distribution shift. In general, models are not guaranteed to perform well when tested on data that has shifted from the training set.

Given this issue, we implement a form of transfer learning known as retraining to combat the natural performance degradation associated with distribution shift in deep learning. This retraining leverages the idea that training and testing the model on more recent market conditions will yield better results. After all, market conditions of a given day tend to be generally more similar to the the day/week before than they are to previous months.

Retraining involves freezing the weights in the first few layers of our network after a certain point, and allowing the other weights to train on more recent data. Here we commence retraining upon reaching an indicated retrain start date in the simulated environment.

We implement two retraining independent schedules: one for daily retraining and another one for weekly retraining. Both retraining schedules involve two sequential stages. In the first stage, all 35,000+ parameters of the model are trained until the specific retrain start date, in this case January 20, 2022. Then, in the second stage, some of the initial layers of the model are frozen and the end ones are allowed to update based on the most recent data, generating many additional models that are tied to being tested for specific dates. This process is depicted in Figure 9

In the case of the daily retraining, the unfrozen parameters are updated at the end of each subsequent day and saved to be tested on the next day. Likewise, in the case of the weekly retraining, the training process updates the unfrozen parameters throughout days which constitute the subsequent trading week. This model is saved and then tested on the next week. These schedules proceed iteratively until all days or weeks being tested are covered by retrained models.

Beyond the freezing of parameters to allow part of the model to adapt to

17
Figure 9: Visual representation of the proposed training and retraining schedule, using a simplified neural network with three input neurons, two hidden layers, and two outputs.

more recent temporally-local conditions, we also recommend the full retraining of the model on a monthly to quarterly basis to ensure it keeps up with longer-scale larger distribution shift.

4.3   Stability Protection Mechanism

Finally, as a system safeguard against volatility, we added a stability-protection mechanism to our timer-set model. In early development, we noted a significant number of one-off adverse markout events during some 30 second periods. This motivated us to design such a mechanism reactive to changes in the NBBO price.

Often these volatility events happen at a much faster frequency than the available timer change cadence, so we developed a method capable of reacting to these events at a more appropriate scale on the order of seconds. We verified that this mechanism improves M-ELO execution quality and

18
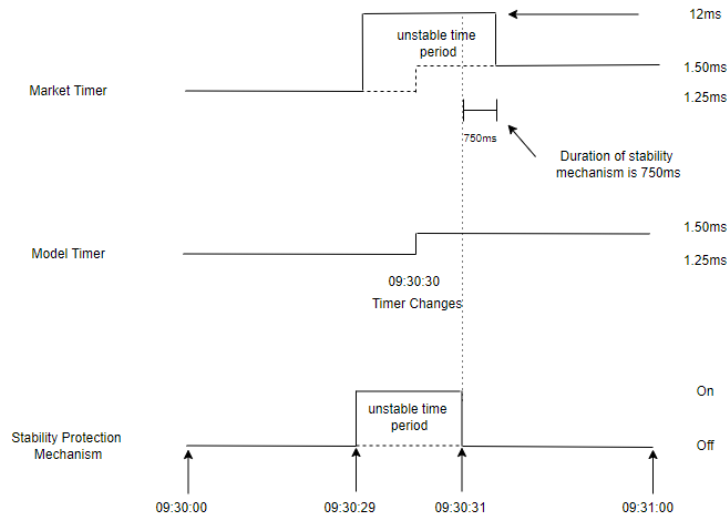

Figure 10: The market timer is set by combining the model timer and the signal from the stability protection mechanism.

performance overall, and protects participants in unstable periods.

Periods which trigger our instability condition (see below) cause the timer to be set to 12ms for 750ms, thereby mitigating negative impact from unfavorable execution. It is important to note that this 750ms duration is independent of the model setting the timer every 30 second period. The market timer is determined by combining the model timer and the stability protection mechanism signal (Figures 11a and 11b). An example of how the stability protection mechanism can improve execution outcomes can be found in Figure 5, from Section 2.2.2

4.3.1 Setting a Stability Threshold

We deem the NBBO unstable if we detect unusually high activity based on the range of NBBO values recorded in the last three seconds. We do this by comparing the range to a threshold for a given ticker and 30 second time interval. The threshold is calculated based on a bisection-quantile method using the previous days' aggregated values (see pseudo-code in 7).

This calculation aims to achieve a certain percent of each day that is

19
(a) Timer movement given stable NBBO prices.
(b) Timer movement given unstable NBBO prices.

Figure 11: Demonstration of stability protection mechanism.

20

considered unstable. Currently, we aim to consider 1.0% of the day unstable, i.e. to have on average 1.0% of time in between the open at 9:30 AM and close at 4:00 PM be considered unstable. This can also be interpreted as flagging only the top 1.0% most unstable regions to trigger the 12ms condition. This level of protection was chosen through substantial experimentation.

While it is possible to envision a more sophisticated way of implementing a protection mechanism based on the NBBO midpoint changing, we have found this one to be sufficiently performant. Planned future further exploration of different thresholds includes moving to an intraday moving average or some sort of varying timeline-weighted threshold.

5 Behavior of Dynamic M-ELO on the Market

Our Dynamic M-ELO timer demonstrates an average combined volume-weighted improvement of 31.7% over the current static 10ms. This includes a 20.3% increase in fill rate and a 11.4% decrease in markout when compared to the current M-ELO and tested over a quarter-long period from January 1, 2022 to April 1, 2022. This corresponds with our retraining period: every date that is tested uses a model that was strictly trained on previous days' information. For more details, please revisit Section 4.2.2.

During this period, the average number of timer changes per day across all symbols was 140 out of a possible 780 (see Figure 16). This means the model decided to dynamically change the timer about 18% of the time, leaving it at the previous set value about three fifths of the time.

Here we explain how we measure performance gains over the current M-ELO timer, review our aggregate results, and present a firm-level analysis that confirms Dynamic M-ELO does not suffer from systematic-bias. Additionally, we thoroughly assess the interpretability of our model's decisions through a feature explainability study.

5.1 How are Gains Measured?

Our results represent an average combined volume-weighted improvement of 31.1% when compared to the static 10ms M-ELO *as represented in our simulation*. We assert the need to compare against the 10ms M-ELO simulation rather than the historical for two important reasons.

First, as mentioned in Section 3.2, our simulation M-ELO trading environment tends to slightly undershoot trades when compared to historical values, so in order to provide an homogeneous metric for comparison, we measure its performance relative to the simulated baseline. Erring on the side of prudence, we note that, as a direct consequence, this methodology provides a rather conservative estimate of performance, when compared to how it would be if using actual historical values as benchmark.

Second, the agent-set timer often results in orders trading that never could have traded at the static value of 10ms (e.g., by getting cancelled before the 10ms have elapsed, but after a hypothetical shorter holding period). This introduces a source of bias when comparing the aggregated markout the agent achieves in different time periods against the historical aggregated markout. If there are more trades, which is often the case, there is more aggregate

22

markout rendering this comparison unreasonable. Instead, we compare the agent-achieved markout with the synthetic markout from shifting the agent-achieved trades to have occurred at the static 10ms holding period.

Given our baseline as outlined above, the respective improvement gains are calculated as follows:

$$\text{FR Improvement (as a \%)} = \frac{\text{FR}_{agent} - \text{FR}_{sim@10}}{\text{FR}_{sim@10}} \qquad (4)$$

$$\text{MO Improvement (as a \%)} = \frac{\text{MO}_{agent} - \text{MO}_{synthetic@10}}{\max(|\text{MO}_{synthetic@10}|, |\text{MO}_{agent}|)} \qquad (5)$$

and added together to give the total improvement. Note that the markout improvement calculation differs from a simple percent. We revised this formula for metrics which can vary between positive and negative values. We found it to provide more robust and conservative comparisons.

Regardless, as can be inferred from Equations 4 and 5, the gains for both metrics are measured following the usual standard convention, i.e., a positive value corresponds with an improvement with respect to the baseline.

5.2   Aggregate Backtest Results

To provide a better idea of the distribution of markout, fill rate, and combined improvement across all symbols, we have broken down our aggregate +20.3% fill rate, +11.4% markout gain result into quartiles as shown in the box-and-whisker plot in Figure 12 and in the descriptive statistics in Table 1. The box-and-whisker plot clearly shows that the combined results are right-skewed, since there are more positive than negative outliers in both fill rate and markout improvement. This means that, beyond the net positive average across symbols, the positive combined improvement happens more frequently than negative loss per-symbol.

Additionally, we benchmarked our model's performance against both static and random timers. This was done to assure that the positive increase in fill rate and decrease in markout can be attributed to the model and not to merely lowering the timer or having it switch randomly between allowable values.

Likewise, for the static timers, we see that the Dynamic M-ELO model outperforms all but the lowest allowable static timer in terms of combined

23
Figure 12: Distribution of fill rate, markout, and combined improvement across tickers. Note that markout and fill rate are treated as independent for their descriptive statistics, so the both column is not just a sum of the other two. For descriptive statistics, see Table 1.

gain, losing only to the .25ms timer by fill rate. However, given the fact that .25ms is the minimum allowed timer value, this actually provides the upperbound for the agent's possible fill rate gain. In terms of markout, Dynamic M-ELO is a clear winner, yielding a substantial net positive markout reduction compared to a static .25ms timer.

5.2.1 Firm-Level Analysis

In order to ensure that our results do not provide an unfair advantage to any specific firm, but rather distribute the gains equitably, we tried to identify patterns and trends that could potentially signify a systematic bias towards specific firms.

24

	MO	FR	Both
Avg	11.4%	20.3%	31.7%
25th Percentile	-1.1%	6.8%	8.0%
50th Percentile	3.8%	11.8%	18.4%
75th Percentile	19.6%	18.0%	38.6%

Table 1: Distribution of fill rate, markout, and combined improvement across tickers. Note that markout and fill rate are treated as independent for their descriptive statistics, so the both column is not just a sum of the other two. See Figure 12 for a box and whisker plot representation.
Figure 13: Dynamic M-ELO results compared with relevant static timers and random switching between allowable timer values. All the metrics in this chart are measured using the static version of M-ELO as baseline.

To this end, we performed a detailed analysis on the distribution of AI-driven gains to assess how they particularly impacted each firm that actively participates in M-ELO, regardless of volume. This yielded satisfactory re-

25

sults: no overall trend emerged, confirming that Dynamic M-ELO will not result in systematic-biased execution towards any one firm.

5.3 Explainability Study

Practical deployment of AI systems is not possible without substantial investigation into how they make their decisions. Indeed, garnering trust for the outcome of the system is wholly dependent on an understanding of how the model works. Here we address any concerns arising from explainability in two ways. First, we present a philosophical discussion of how AI decisions differ from human decisions, and how and why this can be beneficial. Then, we hone in on our model and provide an in-depth analysis of how specific inputs map onto our model's outputted timer change recommendations as well as how the complex interactions between inputs impact the timer duration value.

5.3.1 AI Decision Making

Humans make decisions *ex ante*, meaning they are based on our expectations or predictions of the future. Unfortunately, our predictions of the future are rarely correct and are often clouded by a myriad of obscure, confounding factors. We are limited in three main ways: information overload, biases, and decision fatigue. Information overload is the psychological concept that describes how we cannot leverage all available information due to our limited ability to process it; cognitive and emotional biases covers any deviations from strict rationality, which happen more often then we care to admit; and decision fatigue describes how our fallible brains tire after too much use.

AI systems, on the other hand, do not suffer from information overload or decision fatigue. As for cognitive biases— the likes of hindsight bias— and emotional biases— loss/regret aversion and overconfidence — they can be said to not fall prey to these specific examples as well. A broader discussion of how AI systems can be biased by their training sets, especially when their training sets involve demographic information, is out of the scope of this paper.

Furthermore, AI systems make decisions *a priori*, i.e., strictly based on what they have observed from the past. Throughout the training process, AI systems learn a knowledge base from which to make their decisions. This means that, when trained for one specific task, they can become knowledge

26

domain experts and execute on that task much more efficiently than humans ever could aim to.

Our Dynamic M-ELO model is one such system. It builds its knowledge base to control the duration of the hold period timer, and thereby becomes the equivalent of a subject matter expert timer setting system that can be tasked to deal with the complexity of incoming information and the cadence of decision making without fatigue— unlike a human operator. To the extent that our model is temporally biased to its retraining set, this is by design: our model performs better by adapting to local conditions. The data it ingests is reliable— coming straight from the Nasdaq core internal messaging system.

5.3.2 Feature Sensitivity and Feature Interaction Study

Here we make a case for the explainability of our model's decisions given this reliable data. As stated in Section 3.2, our model ingests 142 features that capture market dynamic information about the continuous book and recent M-ELO activity, as well as other information associated with how the timer impacts the simulation environment. We performed both a localized feature sensitivity analysis and a global feature interaction study to motivate our model's timer-set decisions.

Our feature sensitivity analysis involved varying each feature's value and seeing how changing it (while holding all other features constant) directly impacted the trained model's timer duration decision. The results of this study indicate that, out of the 142 features, 27 have been found to be directly correlated with higher (slower) timers, while 25 have been found to be inversely correlated. For the sake of interpretability, we share some of these below. For a more comprehensive analysis of our feature explainability study, please see Table in Section 7.1 (Appendix 7.1).

Features which, as they increase, tend to contribute toward slowing (increasing) the holding period include: increases in the standard deviation of NBBO prices, number of unique firms placing sell orders on M-ELO, and the volume-weighted average NBBO spread. These factors are all associated with higher volatility of the underlying, and Dynamic M-ELO rightly reacts by increasing the timer to try to combat the possibility of momentarily high markout trades.

On the other hand, features which, as they increase, tend to contribute to speeding up (reducing) the holding period include an increase in the median and maximum number of shares per trade and the number of resting M-ELO

27
Figure 14: Example 30 second time periods resulting in action 1.0 (a), mapping onto a timer decrease of .25ms, and 4.0 (b), mapping onto a timer increase of .5ms.

bids left. These factors are associated with high fill rate, relatively stable periods, and Dynamic M-ELO reacts by decreasing the timer to try to allow as little friction as possible when trading.

Furthermore, we can analyze the interactions between these features and how they contribute to the model's decisions. For example, an increase in the standard deviation of M-ELO buy-side signed markout and a decrease in the median and maximum number of shares per trade was found to be strongly correlated with an increase in timer. Likewise, a decrease in the average NBBO midpoint and an increase in the NBBO price standard deviation, corresponding with a rapid negative change in price, correlate with an increase in timer.

More complicated interactions can be seen in the Shapley value study below, which uses principles from game theory to calculate the marginal contribution of each feature to a model's output [4]. Here we present the ordered top seven influential features that, when combined with all of the other 142 features for a given 30 second time period, give our model's output. It is important to note however, that combining the sum total of the relative impact (Shapley) values yields the maximum Q-value from our model's output and not the actual action itself. This is because the model outputs the Q-values of each action for a given 30 second period, which are argmaxxed to give the model's prescribed relative timer change action. Two examples can be seen in Figure 14b.

28

6   Conclusion

We have proposed a dynamic-timer modification to the Nasdaq Midpoint Extended Life Order (M-ELO) holding period market that, based on our simulation, achieves an increase in fill rate of 20.3% and a decrease in markout of 11.4% compared to the current static 10ms M-ELO timer.

Our Dynamic Timing system leverages AI to evaluate and determine the duration of the M-ELO holding period in relation to everchanging local market conditions. In doing so, it is able to achieve combinations of fill rate and markout results that were previously unreachable by static timers (see Figure 15). We assert that Dynamic M-ELO has shifted the fill rate-markout Pareto frontier towards more favorable trading execution for all parties involved, representing a meaningful innovation.

These overwhelmingly positive results suggest further opportunity to improve market quality with conditionally-attuned products and controls. In an evolving world with more access to data and computational resources than ever before, innovations like Dynamic M-ELO are not only possible and effective, but also represent opportunities to move towards more dynamic market solutions.

29

7.2 Algorithms

7.2.1 D3QN: Modified DDQN Algorithm

Algorithm 1 D3QN: Dynamic M-ELO-DDQN

1: **for** date **d** in $\{$date, end date$\}$ **do**
———————— *Begin Agent Experience Collection* ————————
2:     **for** symbol **s** in $\{$symbols$\}$ **do**
3:         **for** iteration **i** in $780 \times \frac{30 \text{ sec periods}}{1 \text{ day}}$ **do**
4:             Gather and store (state, action, reward, next state) experiences
5:         **end for**
6:     **end for**
———————— *End Agent Experience Collection* ————————
———————— *Begin Agent Training Loop* ————————
7:     **for m** in number of symbols **do**
8:         Sample a batch of (state, action, reward, next state) experiences
9:         **for** experience **e** in $\{$batch$\}$ **do**
10:             Generate target Q-values
11:         **end for**
12:         Calculate loss L
13:         Update main model parameters via gradient descent
14:     **end for**
15:     Update target weights to be evolving weighted linear combination of main model and target model weights
———————— *End Agent Training Loop* ————————
16: **end for**

The training process we implemented for Dynamic M-ELO actually differs from the vanilla DDQN algorithm in several ways [**2**]. First, instead of adding all episodes to the agent's memory, we only add specific episodes which have a non-zero reward, i.e. that return a non-zero fill rate and/or markout value. Additionally, instead of using a single memory buffer, we use a multi-buffer, separating experiences by each component of the reward function to ensure balanced training. Finally, instead of sampling from the buffer at the end of each episode only once, we sample from the buffer a number of times corresponding to the product of the number of ticker times and the number of steps in each training iteration (at the end of every symbol-day).

32

For further details, please see annotated pseudo-code above, which is broken up into two distinct phases— agent experience collection and agent training loop— for ease of understanding.

7.2.2 Stability Coverage Algorithm

Algorithm 2 Quantile-Bisection Stability Coverage Method

1: **for** symbol **s** in $\{$symbols$\}$ **do**
2:     Decide on optimal coverage c^*
3:     Initialize naive price range lower bound l and upper bound u
4:     Compute midpoint m between l and u
5:     Calculate coverage c for m
6:     **while** (l, u) do not offer optimal coverage c^* **do**
7:         **if** $c < c^*$ **then**
8:             Replace the value of u with m
9:         **else**
10:             Replace the value of l with m
11:         **end if**
12:         Update m to be the midpoint of the new l and u
13:         Update c to be the coverage of the new midpoint m
14:     **end while**
15:     Return m as optimal threshold
16: **end for**

FEATURE	Simplified Description
1-trading-days-lookback_MELO-hist-orders_buy-over-total-orders_proportion	Measures the proportion of BUY orders compared to all orders in the M-ELO orderbook over the last day, on a per ticker basis, during regular trading hours.
1-trading-days-lookback_MELO-hist-orders_buy-shares-over-total-shares-orders_proportion	Measures the proportion of shares of BUY orders compared to all shares in the M-ELO orderbook over the last day, on a per ticker basis.
1-trading-days-lookback_MELO-hist-orders_unique-firms-total-orders_count	Measures the count of unique firms that placed orders in the M-ELO orderbook over the last day, on a per ticker basis, during regular trading hours.
1-trading-days-lookback_MELO-hist-orders_unique-firms-buy-orders_count	Measures the count of unique firms that placed BUY orders in the M-ELO orderbook over the last day, on a per ticker basis, during regular trading hours.
1-trading-days-lookback_MELO-hist-orders_unique-firms-sell-orders_count	Measures the count of unique firms that placed SELL orders in the M-ELO orderbook over the last day, on a per ticker basis, during regular trading hours.
5-trading-days-lookback_MELO-hist-orders_buy-over-total-orders_proportion	Measures the proportion of BUY orders compared to all orders in the M-ELO orderbook over the last 5 days, on a per ticker basis, during regular trading hours.
5-trading-days-lookback_MELO-hist-orders_buy-shares-over-total-shares-orders_proportion	Measures the proportion of shares of BUY orders compared to all shares in the M-ELO orderbook over the last 5 days, on a per ticker basis, during regular trading hours.
5-trading-days-lookback_MELO-hist-orders_unique-firms-total-orders_count	Measures the count of unique firms that placed orders in the M-ELO orderbook over the last 5 days, on a per ticker basis, during regular trading hours.
5-trading-days-lookback_MELO-hist-orders_unique-firms-buy-orders_count	Measures the count of unique firms that placed BUY orders in the M-ELO orderbook over the last 5 days, on a per ticker basis, during regular trading hours.
5-trading-days-lookback_MELO-hist-orders_unique-firms-sell-orders_count	Measures the count of unique firms that placed SELL orders in the M-ELO orderbook over the last 5 days, on a per ticker basis, during regular trading hours.
1-trading-days-lookback_NBBO-hist-price_average-bam_price	Average of the historical best ask and best bid prices over the last trading day, per ticker, including after-hours trading.
1-trading-days-lookback_NBBO-hist-price_kurtosis-bam_price	Kurtosis of the distribution of historical best ask and best bid prices over the last trading day, per ticker, including after-hours trading.
1-trading-days-lookback_NBBO-hist-price_max-bam-minus-min-bam_price	Maximum difference between the best ask and best bid prices over the last trading day, per ticker, including after-hours trading.
1-trading-days-lookback_NBBO-hist-price_max-spread-bam_price	Maximum spread (difference between highest bid and lowest ask) over the last trading day, per ticker , including after-hours trading.
1-trading-days-lookback_NBBO-hist-price_skewness-bam_price	Skewness of the distribution of historical best ask and best bid prices over the last trading day, per ticker, including after-hours trading.
1-trading-days-lookback_NBBO-hist-price_standard-deviation-bam_price	Standard deviation of the historical best ask and best bid prices over the last trading day, per ticker, including after-hours trading.
5-trading-days-lookback_NBBO-hist-price_average-bam_price	Average of the historical best ask and best bid prices over the last 5 trading days, per ticker, including after-hours trading.
5-trading-days-lookback_NBBO-hist-price_kurtosis-bam_price	Kurtosis of the distribution of historical best ask and best bid prices over the last 5 trading days, per ticker, including after-hours trading.
5-trading-days-lookback_NBBO-hist-price_max-bam-minus-min-bam_price	Maximum difference between the best ask and best bid prices over the last 5 trading days, per ticker, including after-hours trading.
5-trading-days-lookback_NBBO-hist-price_max-spread-bam_price	Maximum spread (difference between highest bid and lowest ask) over the last 5 trading days, per ticker, including after-hours trading.
5-trading-days-lookback_NBBO-hist-price_skewness-bam_price	Skewness of the distribution of historical best ask and best bid prices over the last 5 trading days, per ticker, including after-hours trading.
5-trading-days-lookback_NBBO-hist-price_standard-deviation-bam_price	Standard deviation of the historical best ask and best bid prices over the last 5 trading days, per ticker, including after-hours trading.
1-trading-days-lookback_NBBO-hist-trades_sum-all-shares-traded_shares	The sum of all the trade volume over the last day, on a ticker-by-ticker basis, including after-hours trading.
1-trading-days-lookback_NBBO-hist-trades_0%-quantile-shares-per-trade_shares	The minimum trade volume over the last day, on a ticker-by-ticker basis, including after-hours trading.
1-trading-days-lookback_NBBO-hist-trades_25%-quantile-shares-per-trade_shares	The 25th percentile of trade volume over the last day, on a ticker-by-ticker basis, including after-hours trading.
1-trading-days-lookback_NBBO-hist-trades_50%-quantile-shares-per-trade_shares	The median trade volume over the last day, on a ticker-by-ticker basis, including after-hours trading.
1-trading-days-lookback_NBBO-hist-trades_75%-quantile-shares-per-trade_shares	The 75th percentile of trade volume over the last day, on a ticker-by-ticker basis, including after-hours trading.
1-trading-days-lookback_NBBO-hist-trades_100%-quantile-shares-per-trade_shares	The maximum trade volume over the last day, on a ticker-by-ticker basis, including after-hours trading.
1-trading-days-lookback_NBBO-hist-trades_average-shares-per-trade_shares	The mean trade volume over the last day, on a ticker-by-ticker basis, including after-hours trading.
5-trading-days-lookback_NBBO-hist-trades_sum-all-shares-traded_shares	The sum of all the trade volume over the last 5 days, on a ticker-by-ticker basis, including after-hours trading.
5-trading-days-lookback_NBBO-hist-trades_0%-quantile-shares-per-trade_shares	The minimum trade volume over the last 5 days, on a ticker-by-ticker basis, including after-hours trading.
5-trading-days-lookback_NBBO-hist-trades_25%-quantile-shares-per-trade_shares	The 25th percentile of trade volume over the last 5 days, on a ticker-by-ticker basis, including after-hours trading.
5-trading-days-lookback_NBBO-hist-trades_50%-quantile-shares-per-trade_shares	The median trade volume over the last 5 days, on a ticker-by-ticker basis, including after-hours trading.
5-trading-days-lookback_NBBO-hist-trades_75%-quantile-shares-per-trade_shares	The 75th percentile of trade volume over the last 5 days, on a ticker-by-ticker basis, including after-hours trading.
5-trading-days-lookback_NBBO-hist-trades_100%-quantile-shares-per-trade_shares	The maximum trade volume over the last 5 days, on a ticker-by-ticker basis, including after-hours trading.
5-trading-days-lookback_NBBO-hist-trades_average-shares-per-trade_shares	The mean trade volume over the last 5 days, on a ticker-by-ticker basis, including after-hours trading.
timer	The current timer in milliseconds (ranges from [0.25, 2.5] inclusive with a step size of 0.25)
FR	Measures the proportion of simulated trades that get traded compared to the total number of orders, per ticker
step_MO_baseline_AT	Average markout of the trades in the baseline model, weighted by the size of the trade, where markout is negative if the trade is a sell-side trade, using 1 second for the markout window, per ticker.
step_MO_baseline_A	Average markout of the trades in the baseline model, only for the trader adding liquidity, weighted by the size of the trade, where markout is negative if the trade is a sell-side trade, using 1 second for the markout window, per ticker.
step_MO_action_AT	Average markout of the trades made by the agent, weighted by the size of the trade, where markout is negative if the trade is a sell-side trade, and using 1 second for the markout window, per ticker.

step_MO_synthetic_AT	Average markout of the trades made by the agent, weighted by the size of the trade, where markout is negative if the trade is a sell-side trade and a corrective timer of (10-timer) is added for the calculation of markout, using 1 second for the markout window, per ticker.
step_MO_action_minus_synthetic_AT	Difference between the average markout of the trades made by the agent, and the average markout of the trades made by the agent, where the corrective timer of (10 - timer) is added for the calculation of markout, taking into account the size of each trade, where markout is negative if it is a sell-side trade, using 1 second for the markout window, per ticker.
step_MO_action_A	Average markout of the trades made by the agent, only for the trader adding liquidity, weighted by the size of the trade, where markout is negative if the trade is a sell-side trade, and using 1 second for the markout window, per ticker.
step_MO_synthetic_A	Average markout of the trades made by the agent, only looking at the trader adding liquidity, weighted by the size of the trade, where markout is negative if the trade is a sell-side trade and a corrective timer of (10-timer) is added for the calculation of markout, using 1 second for the markout window, per ticker.
step_MO_action_minus_synthetic_A	Difference between the average markout of the trades made by the agent, and the average markout of the trades made by the agent, where the corrective timer of (10 - timer) is added for the calculation of markout, and both average markouts are only for the trader adding liquidity, taking into account the size of each trade, where markout is negative if it is a sell-side trade, using 1 second for the markout window, per ticker.
BUY_trade_qty_mean	The average of buyside trade quantity that comes from the simulated trades made by the agent's action, per ticker.
BUY_trade_qty_std	The standard deviation of buyside trade quantity that comes from the simulated trades made by the agent's action, per ticker.
BUY_trade_qty_min	The minimum of buyside trade quantity that comes from the simulated trades made by the agent's action, per ticker.
BUY_trade_qty_max	The maximum of buyside trade quantity that comes from the simulated trades made by the agent's action.
BUY_bam_time_of_trade_mean	Average of the best ask and best bid prices, at the time of each trade, per ticker.
BUY_bam_time_of_trade_std	Standard Deviation of the best ask and best bid prices, at the time of each trade, per ticker.
BUY_bam_time_of_trade_min	Minimum of the best ask and best bid prices, at the time of each trade, per ticker.
BUY_bam_time_of_trade_max	Maximum of the best ask and best bid prices, at the time of each trade, per ticker.
BUY_signed_markout_1000ms_bps_mean	Average of the markouts of the simulated trades in the action model, taking into account the size of each trade, where markout is always positive (buy side), using 1 second for the markout window, per ticker.
BUY_signed_markout_1000ms_bps_std	Standard deviation of the markouts of the simulated trades in the action model, taking into account the size of each trade, where markout is always positive (buy side), using 1 second for the markout window, per ticker.
BUY_signed_markout_1000ms_bps_min	Minimum of the markouts of the simulated trades in the action model, taking into account the size of each trade, where markout is always positive (buy side), using 1 second for the markout window, per ticker.
BUY_signed_markout_1000ms_bps_max	Maximum of the markouts of the simulated trades in the action model, taking into account the size of each trade, where markout is always positive (buy side), using 1 second for the markout window, per ticker.
SELL_trade_qty_mean	The average of sellside trade quantity that comes from the simulated trades made by the agent's action, per ticker.
SELL_trade_qty_std	The standard deviation of sellside trade quantity that comes from the simulated trades made by the agent's action, per ticker.
SELL_trade_qty_min	The minimum of sellside trade quantity that comes from the simulated trades made by the agent's action, per ticker.
SELL_trade_qty_max	The maximum of sellside trade quantity that comes from the simulated trades made by the agent's action.
SELL_bam_time_of_trade_mean	Average of the best ask and best bid prices, at the time of each trade, per ticker.
SELL_bam_time_of_trade_std	Standard Deviation of the best ask and best bid prices, at the time of each trade, per ticker.
SELL_bam_time_of_trade_min	Minimum of the best ask and best bid prices, at the time of each trade, per ticker.
SELL_bam_time_of_trade_max	Maximum of the best ask and best bid prices, at the time of each trade, per ticker.
SELL_signed_markout_1000ms_bps_mean	Average of the signed markouts of the simulated trades in the action model, taking into account the size of each trade, where signed markout is always negative (sell side), using 1 second for the markout window, per ticker.
SELL_signed_markout_1000ms_bps_std	Standard deviation of the signed markouts of the simulated trades in the action model, taking into account the size of each trade, where signed markout is always negative (sell side), using 1 second for the markout window, per ticker.
SELL_signed_markout_1000ms_bps_min	Minimum of the signed markouts of the simulated trades in the action model, taking into account the size of each trade, where signed markout is always negative (sell side), using 1 second for the markout window, per ticker.
SELL_signed_markout_1000ms_bps_max	Maximum of the signed markouts of the simulated trades in the action model, taking into account the size of each trade, where signed markout is always negative (sell side), using 1 second for the markout window, per ticker.
last_step_incl_lookback_BUY_trade_qty_sum	The total buyside trade quantity that came from the simulated trades made by the agent's action over the last 30 seconds, per ticker.
last_step_incl_lookback_BUY_trade_qty_min	The minimum buyside trade quantity that came from the simulated trades made by the agent's action over the last 30 seconds, per ticker.
last_step_incl_lookback_BUY_trade_qty_max	The maximum buyside trade quantity that came from the simulated trades made by the agent's action over the last 30 seconds, per ticker.
last_step_incl_lookback_BUY_trade_qty_mean	The average buyside trade quantity that came from the simulated trades made by the agent's action over the last 30 seconds, per ticker.
last_step_incl_lookback_BUY_trade_qty_stdev	The standard deviation of buyside trade quantity that came from the simulated trades made by the agent's action over the last 30 seconds, per ticker.
last_step_incl_lookback_BUY_trade_qty_kurtosis	The kurtosis of buyside trade quantity that came from the simulated trades made by the agent's action over the last 30 seconds, per ticker.
last_step_incl_lookback_BUY_trade_qty_skew	The skew of buyside trade quantity that came from the simulated trades made by the agent's action over the last 30 seconds, per ticker.
last_step_incl_lookback_SELL_trade_qty_sum	The total sellside trade quantity that came from the simulated trades made by the agent's action over the last 30 seconds, per ticker.
last_step_incl_lookback_SELL_trade_qty_min	The minimum sellside trade quantity that came from the simulated trades made by the agent's action over the last 30 seconds, per ticker.

last_step_incl_lookback_SELL_trade_qty_max	The maximum sellside trade quantity that came from the simulated trades made by the agent's action over the last 30 seconds, per ticker.
last_step_incl_lookback_SELL_trade_qty_mean	The average sellside trade quantity that came from the simulated trades made by the agent's action over the last 30 seconds, per ticker.
last_step_incl_lookback_SELL_trade_qty_stdev	The standard deviation of sellside trade quantity that came from the simulated trades made by the agent's action over the last 30 seconds, per ticker.
last_step_incl_lookback_SELL_trade_qty_kurtosis	The kurtosis of sellside trade quantity that came from the simulated trades made by the agent's action over the last 30 seconds, per ticker.
last_step_incl_lookback_SELL_trade_qty_skew	The skew of sellside trade quantity that came from the simulated trades made by the agent's action over the last 30 seconds, per ticker.
last_3step_incl_lookback_BUY_trade_qty_sum	The total buyside trade quantity that came from the simulated trades made by the agent's action over the last 90 seconds, per ticker.
last_3step_incl_lookback_BUY_trade_qty_min	The minimum buyside trade quantity that came from the simulated trades made by the agent's action over the last 90 seconds, per ticker.
last_3step_incl_lookback_BUY_trade_qty_max	The maximum buyside trade quantity that came from the simulated trades made by the agent's action over the last 90 seconds, per ticker.
last_3step_incl_lookback_BUY_trade_qty_mean	The average buyside trade quantity that came from the simulated trades made by the agent's action over the last 90 seconds, per ticker.
last_3step_incl_lookback_BUY_trade_qty_stdev	The standard deviation of buyside trade quantity that came from the simulated trades made by the agent's action over the last 90 seconds, per ticker.
last_3step_incl_lookback_BUY_trade_qty_kurtosis	The kurtosis of buyside trade quantity that came from the simulated trades made by the agent's action over the last 90 seconds, per ticker.
last_3step_incl_lookback_BUY_trade_qty_skew	The skew of buyside trade quantity that came from the simulated trades made by the agent's action over the last 90 seconds, per ticker.
last_3step_incl_lookback_SELL_trade_qty_sum	The total sellside trade quantity that came from the simulated trades made by the agent's action over the last 90 seconds, per ticker.
last_3step_incl_lookback_SELL_trade_qty_min	The minimum sellside trade quantity that came from the simulated trades made by the agent's action over the last 90 seconds, per ticker.
last_3step_incl_lookback_SELL_trade_qty_max	The maximum sellside trade quantity that came from the simulated trades made by the agent's action over the last 90 seconds, per ticker.
last_3step_incl_lookback_SELL_trade_qty_mean	The average sellside trade quantity that came from the simulated trades made by the agent's action over the last 90 seconds, per ticker.
last_3step_incl_lookback_SELL_trade_qty_stdev	The standard deviation of sellside trade quantity that came from the simulated trades made by the agent's action over the last 90 seconds, per ticker.
last_3step_incl_lookback_SELL_trade_qty_kurtosis	The kurtosis of sellside trade quantity that came from the simulated trades made by the agent's action over the last 90 seconds, per ticker.
last_3step_incl_lookback_SELL_trade_qty_skew	The skew of sellside trade quantity that came from the simulated trades made by the agent's action over the last 90 seconds, per ticker.
last_5_min_incl_lookback_BUY_trade_qty_sum	The total buyside trade quantity that came from the simulated trades made by the agent's action over the last 5 minutes, per ticker.
last_5_min_incl_lookback_BUY_trade_qty_min	The minimum buyside trade quantity that came from the simulated trades made by the agent's action over the last 5 minutes, per ticker.
last_5_min_incl_lookback_BUY_trade_qty_max	The maximum buyside trade quantity that came from the simulated trades made by the agent's action over the last 5 minutes, per ticker.
last_5_min_incl_lookback_BUY_trade_qty_mean	The average buyside trade quantity that came from the simulated trades made by the agent's action over the last 5 minutes, per ticker.
last_5_min_incl_lookback_BUY_trade_qty_stdev	The standard deviation of buyside trade quantity that came from the simulated trades made by the agent's action over the last 5 minutes, per ticker.
last_5_min_incl_lookback_BUY_trade_qty_kurtosis	The kurtosis of buyside trade quantity that came from the simulated trades made by the agent's action over the last 5 minutes, per ticker.
last_5_min_incl_lookback_BUY_trade_qty_skew	The skew of buyside trade quantity that came from the simulated trades made by the agent's action over the last 5 minutes, per ticker.
last_5_min_incl_lookback_SELL_trade_qty_sum	The total sellside trade quantity that came from the simulated trades made by the agent's action over the last 5 minutes, per ticker.
last_5_min_incl_lookback_SELL_trade_qty_min	The minimum sellside trade quantity that came from the simulated trades made by the agent's action over the last 5 minutes, per ticker.
last_5_min_incl_lookback_SELL_trade_qty_max	The maximum sellside trade quantity that came from the simulated trades made by the agent's action over the last 5 minutes, per ticker.
last_5_min_incl_lookback_SELL_trade_qty_mean	The average sellside trade quantity that came from the simulated trades made by the agent's action over the last 5 minutes, per ticker.
last_5_min_incl_lookback_SELL_trade_qty_stdev	The standard deviation of sellside trade quantity that came from the simulated trades made by the agent's action over the last 5 minutes, per ticker.
last_5_min_incl_lookback_SELL_trade_qty_kurtosis	The kurtosis of sellside trade quantity that came from the simulated trades made by the agent's action over the last 5 minutes, per ticker.
last_5_min_incl_lookback_SELL_trade_qty_skew	The skew of sellside trade quantity that came from the simulated trades made by the agent's action over the last 5 minutes, per ticker.
last_10_min_incl_lookback_BUY_trade_qty_sum	The total buyside trade quantity that came from the simulated trades made by the agent's action over the last 10 minutes, per ticker.
last_10_min_incl_lookback_BUY_trade_qty_min	The minimum buyside trade quantity that came from the simulated trades made by the agent's action over the last 10 minutes, per ticker.
last_10_min_incl_lookback_BUY_trade_qty_max	The maximum buyside trade quantity that came from the simulated trades made by the agent's action over the last 10 minutes, per ticker.
last_10_min_incl_lookback_BUY_trade_qty_mean	The average buyside trade quantity that came from the simulated trades made by the agent's action over the last 10 minutes, per ticker.
last_10_min_incl_lookback_BUY_trade_qty_stdev	The standard deviation of buyside trade quantity that came from the simulated trades made by the agent's action over the last 10 minutes, per ticker.
last_10_min_incl_lookback_BUY_trade_qty_kurtosis	The kurtosis of buyside trade quantity that came from the simulated trades made by the agent's action over the last 10 minutes, per ticker.
last_10_min_incl_lookback_BUY_trade_qty_skew	The skew of buyside trade quantity that came from the simulated trades made by the agent's action over the last 10 minutes, per ticker.
last_10_min_incl_lookback_SELL_trade_qty_sum	The total sellside trade quantity that came from the simulated trades made by the agent's action over the last 10 minutes, per ticker.
last_10_min_incl_lookback_SELL_trade_qty_min	The minimum sellside trade quantity that came from the simulated trades made by the agent's action over the last 10 minutes, per ticker.
last_10_min_incl_lookback_SELL_trade_qty_max	The maximum sellside trade quantity that came from the simulated trades made by the agent's action over the last 10 minutes, per ticker.

last_10_min_incl_lookback_SELL_trade_qty_mean	The average sellside trade quantity that came from the simulated trades made by the agent's action over the last 10 minutes, per ticker.
last_10_min_incl_lookback_SELL_trade_qty_stdev	The standard deviation of sellside trade quantity that came from the simulated trades made by the agent's action over the last 10 minutes, per ticker.
last_10_min_incl_lookback_SELL_trade_qty_kurtosis	The kurtosis of sellside trade quantity that came from the simulated trades made by the agent's action over the last 10 minutes, per ticker.
last_10_min_incl_lookback_SELL_trade_qty_skew	The skew of sellside trade quantity that came from the simulated trades made by the agent's action over the last 10 minutes, per ticker.
last_30_min_incl_lookback_BUY_trade_qty_sum	The total buyside trade quantity that came from the simulated trades made by the agent's action over the last 30 minutes, per ticker.
last_30_min_incl_lookback_BUY_trade_qty_min	The minimum buyside trade quantity that came from the simulated trades made by the agent's action over the last 30 minutes, per ticker.
last_30_min_incl_lookback_BUY_trade_qty_max	The maximum buyside trade quantity that came from the simulated trades made by the agent's action over the last 30 minutes, per ticker.
last_30_min_incl_lookback_BUY_trade_qty_mean	The average buyside trade quantity that came from the simulated trades made by the agent's action over the last 30 minutes, per ticker.
last_30_min_incl_lookback_BUY_trade_qty_stdev	The standard deviation of buyside trade quantity that came from the simulated trades made by the agent's action over the last 30 minutes, per ticker.
last_30_min_incl_lookback_BUY_trade_qty_kurtosis	The kurtosis of buyside trade quantity that came from the simulated trades made by the agent's action over the last 30 minutes, per ticker.
last_30_min_incl_lookback_BUY_trade_qty_skew	The skew of buyside trade quantity that came from the simulated trades made by the agent's action over the last 30 minutes, per ticker.
last_30_min_incl_lookback_SELL_trade_qty_sum	The total sellside trade quantity that came from the simulated trades made by the agent's action over the last 30 minutes, per ticker.
last_30_min_incl_lookback_SELL_trade_qty_min	The minimum sellside trade quantity that came from the simulated trades made by the agent's action over the last 30 minutes, per ticker.
last_30_min_incl_lookback_SELL_trade_qty_max	The maximum sellside trade quantity that came from the simulated trades made by the agent's action over the last 30 minutes, per ticker.
last_30_min_incl_lookback_SELL_trade_qty_mean	The average sellside trade quantity that came from the simulated trades made by the agent's action over the last 30 minutes, per ticker.
last_30_min_incl_lookback_SELL_trade_qty_stdev	The standard deviation of sellside trade quantity that came from the simulated trades made by the agent's action over the last 30 minutes, per ticker.
last_30_min_incl_lookback_SELL_trade_qty_kurtosis	The kurtosis of sellside trade quantity that came from the simulated trades made by the agent's action over the last 30 minutes, per ticker.
last_30_min_incl_lookback_SELL_trade_qty_skew	The skew of sellside trade quantity that came from the simulated trades made by the agent's action over the last 30 minutes, per ticker.
asks_left_in_book	The total amount of eligible shares per price level on the ask side, that remain in the melo order book at a given point in time, per ticker.
bids_left_in_book	The total amount of eligible shares per price level on the bid side, that remain in the melo order book at a given point in time, per ticker.

Glossary:

Agent	Used interchangeably with the Dynamic M-ELO Reinforcement Learning based holding timer deciding system, excluding the Instability Protection System. See White Paper, section 3.1, "Reinforcement learning"
Simulation	Replication of the M-ELO trading environment with varying holding period timer, which allows for the model to interact and learn about optimal market conditions. See White Paper, section 3.2, "Developing a Simulation of M-ELO with a Non-Static Holding Period"
Synthetic	Evaluation of trade conditions corresponding to shifting the timestamp at which a trade occurred, per our simulation, to the timing corresponding to a hypothethical analogous trade with a static timer of 10ms, to ensure that we measure gains in a comparable, fair scale. See White Paper, section 5.1, "How are Gains Measured?"
Standard Deviation	Standard deviation measures the spread or dispersion of data points around the mean. It indicates how much the values deviate from the average.
Skewness	Skewness measures the asymmetry of a probability distribution. It indicates whether the data is skewed to the left (negative skew) or to the right (positive skew) of the mean.
Kurtosis	Kurtosis measures the peakedness or flatness of a probability distribution. It indicates whether the data has a sharp peak (leptokurtic) or a flatter shape (platykurtic) compared to a normal distribution.
Markout	See White Paper, section 2.2.1, "Defining Fill Rate and Markout"
Fill rate	See White Paper, section 2.2.1, "Defining Fill Rate and Markout"
Buyside trade attribute	Evaluation of trade attributes corresponding to the perspective of the buyer of the instrument
Sellside trade attribute	Evaluation of trade attributes corresponding to the perspective of the seller of the instrument
White Paper	Diana Kafkes et al., "Applying Artificial Intelligence & Reinforcement Learning Methods Towards Improving Execution Outcomes," SSRN, October 19, 2022, available at https://papers.ssrn.com/sol3/papers.cfm?abstract_id=4243985 (the "White Paper")

4702. Order Types

(a) No change.

(b) Except where stated otherwise, the following Order Types are available to all Participants:

   (1) – (13) No change.

   (14) (A) A "Midpoint Extended Life Order" is an Order Type with a Non-Display Order Attribute that is priced at the midpoint between the NBBO and that will not be eligible to execute until a minimum time period ("Holding Period") has passed after acceptance of the Order by the System. Eligible Midpoint Extended Life Orders may only execute against other eligible Midpoint Extended Life Orders and M-ELO+CB Orders. Buy (sell) Midpoint Extended Life Orders will be ranked in time order at the midpoint among other Buy (Sell) Midpoint Extended Life Orders and buy (sell) MELO+ CB Orders. A Midpoint Extended Life Order may be cancelled at any time. If a Midpoint Extended Life Order is modified by a member (other than to decrease the size of the Order or to modify the marking of a sell Order as long, short, or short exempt) during the Holding Period, the System will restart the Holding Period. If a Midpoint Extended Life Order is modified by a member (other than to decrease the size of the Order or to modify the marking of a sell Order as long, short, or short exempt) after it is eligible to execute, the Order will have to satisfy a new Holding Period to become eligible to execute.

   At the commencement of Market Hours, the initial Holding Period for a Midpoint Extended Life Order in a particular symbol will be 1.25 milliseconds. However, the System may, based upon its proprietary assessment of market conditions for that symbol, decide to vary the default Holding Period of all Midpoint Extended Life Orders in a symbol in increments of 0.25 or 0.50 milliseconds, and within an overall range of between 0.25 and 2.50 milliseconds during normal market conditions

(described below), beginning 30 seconds after Market Hours commences and then at 30 second intervals thereafter until Market Hours conclude ("Change Events"). Whenever a Midpoint Extended Life Order in a symbol enters the Exchange Book during Market Hours, it will adopt the then-prevailing Holding Period that the System chose for all Midpoint Extended Life Orders in that symbol as of the immediately preceding Change Event. The Holding Period for the Midpoint Extended Life Order will not be eligible for modification until the next scheduled Change Event occurs for all Midpoint Extended Life Orders in that symbol, at which point all pending Midpoint Extended Life Orders in a symbol with unexpired Holding Periods will adopt the modifications that the System then makes to the Holding Period (retroactive to the time of acceptance of the Midpoint Extended Life Orders).

For purposes of this rule, the phrase "proprietary assessment of market conditions" refers to the Exchange's evaluation of prevailing market conditions for a given symbol using an algorithm programmed to set a Holding Period duration which, at each Change Event, achieves an optimal blend of two objectives: maximization of M-ELO fill rates; and minimization of M-ELO mark-out rates. For this purpose, the algorithm ingests and analyzes 142 data points, which the Exchange identifies and describes in Exhibit 3b of SR-NASDAQ-2022-079 Amendment 2, which is available on the Exchange's website. The Exchange derives these data from a combination of public data and M-ELO data feeds. Furthermore, the Exchange conducts weekly re-trainings of the algorithm, outside of Market Hours, to improve its performance relative to the immediately preceding period (in terms of the two aforementioned objectives). The Exchange deploys a retrained version of the algorithm only if it determines that doing so will, in fact, improve its performance relative to the immediately preceding period. The Exchange provides further information about the algorithm and the retraining process in a White Paper attached as Exhibit 3a to SR-NASDAQ-2022-079 Amendment 2, which is available on the Exchange's website.

Notwithstanding the above, whenever the System determines that market conditions for a symbol have become extraordinarily unstable (including in between Change Events), the System will activate a stability protection mechanism. The stability protection mechanism will override the prevailing Holding Period for a Midpoint Extended Life Order in a symbol experiencing extraordinary instability and immediately increase the duration of the Holding Period to 12 milliseconds for a period of at least 750 milliseconds (the "Stability Protected Period"). The System may activate the stability protection mechanism even between Change Events. The System will evaluate, at each NBBO update, whether market conditions remain extraordinarily unstable and, if so, it will restart the 750ms Stability Protected Period and maintain the 12ms Holding Period until conditions stabilize. Once the System determines that market conditions have stabilized (i.e., all measurements for the symbol are at or below the threshold value throughout the duration of the prevailing Stability Protected Period), the System will revert the duration of the Holding Periods to that which prevailed as of the Change Event that occurred immediately

prior to the activation of the stability protection mechanism or, if the stability protection mechanism was active when a Change Event occurred, to the duration selected at the immediately preceding Change Event. The System will then proceed to reevaluate the duration of the Holding Periods as per the regular schedule of Change Events. For purposes of this Rule, the System determines that "extraordinary instability" for a symbol exists through observations it makes following every change in the NBBO for that symbol that occurs during the trading day. When the NBBO changes, the System looks back at the prior three seconds of trading and measures the difference between the highest and the lowest NBBO midpoint values that occurred during that period, and then it compares that measurement to a threshold value for the symbol. The System concludes that extraordinary instability exists for a symbol if the measurement exceeds the threshold value. The threshold value for a symbol, in turn, is the difference between the highest and the lowest NBBO midpoint values for the symbol that, if applied to its trading activity during the prior trading day, would have caused the System to deem trading in the symbol to be extraordinarily unstable for as close to one percent of that day as possible.

4702. Order Types

(a) No change.

(b) Except where stated otherwise, the following Order Types are available to all Participants:

  (1) – (13) No change.

  (14) (A) A "Midpoint Extended Life Order" is an Order Type with a Non-Display Order Attribute that is priced at the midpoint between the NBBO and that will not be eligible to execute until a minimum time period [of 10 milliseconds]("Holding Period") has passed after acceptance of the Order by the System. Eligible Midpoint Extended Life Orders may only execute against other eligible Midpoint Extended Life Orders and M-ELO+CB Orders. Buy (sell) Midpoint Extended Life Orders will be ranked in time order at the midpoint among other Buy (Sell) Midpoint Extended Life Orders and buy (sell) MELO+ CB Orders. A Midpoint Extended Life Order may be cancelled at any time. If a Midpoint Extended Life Order is modified by a member (other than to decrease the size of the Order or to modify the marking of a sell Order as long, short, or short exempt) during the Holding Period, the System will restart the Holding Period. If a Midpoint Extended Life Order is modified by a member (other than to decrease the size of the Order or to modify the marking of a sell Order as long, short, or short exempt) after it is eligible to execute, the Order will have to satisfy a new Holding Period to become eligible to execute.

  At the commencement of Market Hours, the initial Holding Period for a Midpoint Extended Life Order in a particular symbol will be 1.25 milliseconds. However, the System may, based upon its proprietary assessment of market conditions for that symbol, decide to vary the default Holding Period of all Midpoint Extended Life Orders in a symbol in increments of 0.25 or 0.50 milliseconds, and within an overall range of between 0.25 and 2.50 milliseconds during normal market conditions (described below), beginning 30 seconds after Market Hours commences and then at 30 second intervals thereafter until Market Hours conclude ("Change Events"). Whenever a Midpoint Extended Life Order in a symbol enters the Exchange Book

during Market Hours, it will adopt the then-prevailing Holding Period that the System chose for all Midpoint Extended Life Orders in that symbol as of the immediately preceding Change Event. The Holding Period for the Midpoint Extended Life Order will not be eligible for modification until the next scheduled Change Event occurs for all Midpoint Extended Life Orders in that symbol, at which point all pending Midpoint Extended Life Orders in a symbol with unexpired Holding Periods will adopt the modifications that the System then makes to the Holding Period (retroactive to the time of acceptance of the Midpoint Extended Life Orders).

For purposes of this rule, the phrase "proprietary assessment of market conditions" refers to the Exchange's evaluation of prevailing market conditions for a given symbol using an algorithm programmed to set a Holding Period duration which, at each Change Event, achieves an optimal blend of two objectives: maximization of M-ELO fill rates; and minimization of M-ELO mark-out rates. For this purpose, the algorithm ingests and analyzes 142 data points, which the Exchange identifies and describes in Exhibit 3b of SR-NASDAQ-2022-079 Amendment 2, which is available on the Exchange's website. The Exchange derives these data from a combination of public data and M-ELO data feeds. Furthermore, the Exchange conducts weekly re-trainings of the algorithm, outside of Market Hours, to improve its performance relative to the immediately preceding period (in terms of the two aforementioned objectives). The Exchange deploys a retrained version of the algorithm only if it determines that doing so will, in fact, improve its performance relative to the immediately preceding period. The Exchange provides further information about the algorithm and the retraining process in a White Paper attached as Exhibit 3a to SR-NASDAQ-2022-079 Amendment 2, which is available on the Exchange's website.

Notwithstanding the above, whenever the System determines that market conditions for a symbol have become extraordinarily unstable (including in between Change Events), the System will activate a stability protection mechanism. The stability protection mechanism will override the prevailing Holding Period for a Midpoint Extended Life Order in a symbol experiencing extraordinary instability and immediately increase the duration of the Holding Period to 12 milliseconds for a period of at least 750 milliseconds (the "Stability Protected Period"). The System may activate the stability protection mechanism even between Change Events. The System will evaluate, at each NBBO update, whether market conditions remain extraordinarily unstable and, if so, it will restart the 750ms Stability Protected Period and maintain the 12ms Holding Period until conditions stabilize. Once the System determines that market conditions have stabilized (i.e., all measurements for the symbol are at or below the threshold value throughout the duration of the prevailing Stability Protected Period), the System will revert the duration of the Holding Periods to that which prevailed as of the Change Event that occurred immediately prior to the activation of the stability protection mechanism or, if the stability protection mechanism was active when a Change Event occurred, to the duration selected at the immediately preceding Change Event. The System will then proceed

to reevaluate the duration of the Holding Periods as per the regular schedule of Change Events. For purposes of this Rule, the System determines that "extraordinary instability" for a symbol exists through observations it makes following every change in the NBBO for that symbol that occurs during the trading day. When the NBBO changes, the System looks back at the prior three seconds of trading and measures the difference between the highest and the lowest NBBO midpoint values that occurred during that period, and then it compares that measurement to a threshold value for the symbol. The System concludes that extraordinary instability exists for a symbol if the measurement exceeds the threshold value. The threshold value for a symbol, in turn, is the difference between the highest and the lowest NBBO midpoint values for the symbol that, if applied to its trading activity during the prior trading day, would have caused the System to deem trading in the symbol to be extraordinarily unstable for as close to one percent of that day as possible.

If a limit price is assigned to a Midpoint Extended Life Order, the Order will be: (1) eligible for execution in time priority if upon acceptance of the Order by the System, the midpoint price is within the limit set by the participant; or (2) held until the midpoint falls within the limit set by the participant at which time the Holding Period will commence and thereafter the System will make the Order eligible for execution in time priority. For example, if the Best Bid was $11 and the Best Offer was $11.06, the price of the Midpoint Extended Life Order would be $11.03. If a participant enters a Midpoint Extended Life Order to buy with a limit of $11.02, the Holding Period would not begin until the midpoint price reached $11.02. If a Midpoint Extended Life Order has met the Holding Period requirement but the midpoint is no longer within its limit, it will nonetheless be ranked in time priority among other Midpoint Extended Life Orders and M-ELO+CBs if the NBBO later moves such that it is within the Order's limit price. Midpoint Extended Life Orders will not execute if there is a resting non-displayed Order priced more aggressively than the midpoint between the NBBO, and will be held for execution until the resting non-displayed Order is no longer on the Nasdaq Book or the midpoint of the NBBO matches the price of the resting non-displayed Order.

Midpoint Extended Life Orders in existence at the time a halt is initiated will be ineligible to execute and held by the System until trading has resumed and the NBBO has been received by Nasdaq. Upon resumption of trading in a halted symbol, any new Midpoint Extended Life Order in that symbol and any pending Midpoint Extended Life Order in that symbol with an unexpired Holding Period will be subject to a 12 milliseconds Holding Period (running from the time when trading resumes) until the next scheduled Change Event, at which point the System may determine to adjust that Holding Period to a duration within the range applicable under normal market conditions. If, however, the System determines that extraordinary instability in the symbol exists, it may instead determine to activate the stability protection mechanism and maintain the duration of the Holding Period at 12 milliseconds for another 750 milliseconds. Prior to commencement of a new 12 millisecond Holding Period for a new or pending M-ELO or M-ELO+CB

<u>following a Halt, the System will first determine whether the M-ELO or M-ELO+CB is or remains eligible for execution. That is, the Holding Period will commence only if, upon commencement of trading following the Halt, the midpoint price for the Order is within the limit set by the participant. If not, the System will hold the Order until the midpoint falls within the limit set by the participant, at which time the 12 millisecond Holding Period will commence.</u>

Nasdaq will publish on Nasdaqtrader.com weekly aggregated number of shares and transactions of Midpoint Extended Life Orders executed on Nasdaq by security. The weekly aggregated data would be published with a delay of two weeks for NMS stocks in Tier 1 of the NMS Plan to Address Extraordinary Market Volatility, and four weeks for all other NMS stocks. Nasdaq will also publish on Nasdaqtrader.com monthly aggregated block-sized trading statistics of total shares and total transactions of Midpoint Extended Life Orders executed on Nasdaq. A transaction would be considered "block-sized" if it meets any of the following categories of criteria: (1) 10,000 or more shares; (2) $200,000 or more in value; (3) 10,000 or more shares and $200,000 or more in value; (4) 2,000 to 9,999 shares; (5) $100,000 to $199,999 in value; or (6) 2,000 to 9,999 shares and $100,000 to $199,999 in value. For each of these categories, Nasdaq will publish monthly transaction count and share executed volume information. The data will be published no earlier than one month following the end of the month for which trading was aggregated.

(B) The following Order Attributes may be assigned to a Midpoint Extended Life Order:

• Minimum Quantity.

• Size.

• Time-in-Force. Regardless of the Time-in-Force entered, a Midpoint Extended Life Order may not be active outside of Market Hours. A Midpoint Extended Life Order entered during Pre-Market Hours will be held by the System in time priority until Market Hours. Midpoint Extended Life Orders entered during Post-Market Hours will not be accepted by the System. A Midpoint Extended Life Order remaining unexecuted after 4:00 p.m. ET will be cancelled by the System. If a Midpoint Extended Life Order is entered with a Time-In-Force of IOC, it will execute against available eligible resting interest immediately upon the expiration of the Holding Period; if no such resting interest is available, or shares of the Order remain unexecuted after executing against eligible resting interest, then the System will automatically cancel the Order or the remaining shares of the Order, as applicable; if the Order is ineligible to begin the Holding Period upon entry, then the System will cancel it immediately.

• Non-Display. All Midpoint Extended Life Orders are Non-Displayed.

(15) A "Midpoint Extended Life Order Plus Continuous Book" or "M-ELO+CB" is an Order Type that has all of the characteristics and attributes of a Midpoint Extended Life Order, as set forth above in subparagraph (14), except as follows:

- A M-ELO+CB that satisfies the Holding Period shall be eligible to execute (at the midpoint of the NBBO) against other eligible M-ELO+CBs, eligible Midpoint Extended Life Orders, and as described below, Non-Displayed Orders with Midpoint Pegging and Midpoint Peg Post-Only Orders (collectively, "Midpoint Orders") resting on the Exchange's Continuous Book. A M-ELO+CB shall be eligible to execute against a Midpoint Order if: (i) the Midpoint Order has the [Midpoint]Trade Now Attribute enabled; (ii) no other order is resting on the Continuous Book that has a more aggressive price than the current midpoint of the NBBO; (iii) the Midpoint Order has rested on the Exchange's Continuous Book for a minimum of [10 milliseconds]the duration of the Holding Period then applicable to a M-ELO+CB in that symbol after the NBBO midpoint falls within the limit set by the participant; and (iv) the Midpoint Order satisfies any minimum quantity requirement of the M-ELO+CB. A buy (sell) M-ELO+CB will be ranked in time order at the midpoint among other buy (sell) M-ELO+CBs, buy (sell) Midpoint Extended Life Orders, and buy (sell) Midpoint Orders, as of the time when such Orders become eligible to execute.

- QIX is not available for the entry of a M-ELO+CB.

- Nasdaq will include M-ELO+CB executions in the statistical information it publishes on Nasdaqtrader.com for M-ELOs.
